1909

**DOMESTIC.—FIRST CLASS.**—Letters 2 cts. per oz. or fraction thereof. A "Special Delivery" ten cent stamp, or ten cents in ordinary stamps, and the words "Special Delivery" marked on the envelope or wrapper in addition to the lawful postage, entitles the letter to immediate delivery at, or within one mile of, any post-office. Postal Cards 1 ct. each.

**SECOND-CLASS.**—Newspapers, magazines, and other periodicals, issued at stated intervals, at least four times a year; 1 ct. for each 4 ozs., payable by postage stamps.

**THIRD CLASS.**—Printed books, pamphlets, circulars, engravings, lithographs, proof-sheets and manuscript accompanying the same, etc. Circulars produced by hektograph or similar process. The limit of weight four pounds, except in the case of single books. The rate of postage on mail matter of the third class is 1 ct. for each 2 ozs., or fraction thereof.

**FOURTH CLASS.**—All mailable matter not included in the three preceding classes, which is so prepared for mailing as to be easily taken from the wrapper and examined. Rate, 1 ct. per oz. or fraction thereof, except seeds, roots, cuttings, bulbs, plants and scions, which are 1 ct. per 2 ozs. Limit of weight, four lbs. Full prepayment compulsory. Registry fee, eight cents.

**FEE CHARGED FOR MONEY-ORDERS.**—For Orders from \$0.01 to \$2.50, 3c.; \$2.51 to \$5.00, 5c.; \$5.01 to \$10.00, 8c.; \$10.01 to \$20.00, 10c.; \$20.01 to \$30.00, 12c.; \$30.01 to \$40.00, 15c.; \$40.01 to \$50.00, 18c.; \$50.01 to \$60.00, 20c.; \$60.01 to \$75.00, 25c.; \$75.01 to \$100.00, 30c.

**FOREIGN.**—To all foreign countries except as mentioned below: Letters for first oz. or less 5 cts.; each additional oz. or fraction, 3 cts. Single Postal Cards (including souvenir) 2 cts. Double Postal Cards 4 cts. Printed matter, all kinds, each 2 ozs. or fraction of 2 ozs., 1 ct. Commercial Papers, first 10 ozs. or less, 5 cts.; each additional 2 ozs. or fraction of 2 ozs., 1 ct. Samples Merchandise, first 4 ozs. or less, 2 cts.; each additional 2 ozs. or fraction of 2 ozs., 1 ct. Registration fee in addition to postage, 8 cts.

Articles of every kind or nature which are admitted to the domestic mails of the United States, will be admitted under the same conditions, to the mails for Canada, Cuba, Mexico and the Republic of Panama, except that commercial papers and bona fide trade samples are transmissible in the regular mails at the postage rate and subject to the conditions applicable to those articles in Postal Union mails. Packages—other than single volumes of printed books—the weight of which exceeds four pounds six ounces, are excluded from the mails for Cuba, Mexico and the Republic of Panama. Sealed packages other than letters in their usual and ordinary form, are unmailable to Canada, Cuba, Mexico and the Republic of Panama.

Mail matter for Hawaii, Porto Rico, the Philippines, the islands of Guam and Tutuila, the "Canal Zone," and Shanghai, China, is subject to domestic rates and conditions.

**INTERNATIONAL OR FOREIGN MONEY-ORDER FEES.**—\$0.01 to \$10.00, 10c.; \$10.01 to \$20.00, 20c. etc. to \$100.00, \$1.00.

Tuesday, Aug. 12, 1924.

Walked about Lewis to see the old  
 geology that I have looked at so often. Saw  
 nothing new. By afternoon begin to  
 feel better.

Wednesday, Aug. 13, 1924

Concluded to go on to Port Daniel and  
 get my ticket and berth to Watapedia.

Then went over again to Lewis, and  
 once especially to see the relation of the  
 red Sillery to the older Lewis. At Point  
Lewis the contact of the two formations is  
 well exposed. Here however all is so much  
 jumbled that one may argue for either  
 or for an igneous contact. Well along to the  
 south from Lewis railway station <sup>to Port Daniel</sup> one sees  
 a zone of thick bedded limestones folded,  
 marked and abounding in small faults. How-  
 ever one does not get out of this zone until  
 one gets to Point Lewis - the old abandoned  
 P.R. station. Here there first appears above  
 the limestones the regular green shales, and then

Wea.

FRI. JAN. 8, 1909

The whole stratigraphic succession is very obscure. It  
is that a case is marked that one cannot make out  
the sequences.

Wea.

~~SAT. JAN. 9, 1909~~

Ther.

red sandy shales, followed by <sup>more</sup> green shales. Then a transition series into the Regulation red shales of the Sillery. Probably most geologists would say then it has a complete sequence one from the other, but which of the two formations is the older is not clear. The general inference would be that the Lewis is the older.

Then climbed up the turnpike that goes east into Moine, to see the fine field figured by Raymond in the Guide Book to the St. Channon. It is a fine closed field, nearly vertical but seeming to dip a, becomes more a low mountain. On going into Upper Town of Lewis, all I could see was the Regulation banded green shale of the Lewis.

Then to the Falls north of the Lewis Ferry. Here one sees the thin bedded limestone of the Admiral's zone. Otherwise all is green shale. Are there <sup>shaly limestone</sup> the thick bedded limestone along the road to Point Lewis. If so then I should say as we go to the red shales one appears to go down in the section, making the Sillery older than the Lewis. Certainly they are not above the

Wea.

SUN. JAN. 10, 1909

Ther.

Above the wooden steps we may have above the Pu-  
 mardio zone the first red zone seen earlier at  
 Point Lewis. However I did not see beyond the  
 repetition Liller.

If Raymond's section is correct, I see no  
 objection to it, and if the sequence keeps on as one  
 goes south along the St. Lawrence, then the red  
 Liller must be on top of the Lewis. Then how  
 about the thick Languan sandstone at the Quebec  
 bridge: Are they at the base or at the top? If  
 the latter then we have another case of an  
 emergent sandstone and conglomerate.

Wea.

Mon. ~~JAN. 11, 1909~~

Ther.

Humadia zone.

As I got to the top of the stairs and of a short  
 shut to the street with the street car, I found  
 on a zone of red and green shales, and then the  
 regular green shales of the Lewis. But beyond  
 one does not get into the zone of red shales  
 of the Hill.

I then walked north along the street-car street  
 into Langson and then went down a road across  
 the limestone conglomerate of Big Hill. I saw  
 again the boulders with cephalopods, and gastropods.  
 At the base of this li. congl. the li. boulders  
 are largest, some are well rounded, but in the  
 main they are slabs of thin bedded li. with the  
 beds well rounded. There are <sup>in</sup> boulders of  
 gitty green shales and of other shales. Some pieces  
 are apt to be twice as large as the li. Between  
 some of the li. bedding mud was laid down  
 a great deal with the general condition that the li. congl.  
 were laid down in a mixed sea.

In two different places I saw gitty green shale  
 boulders one for each in the regular intra-  
 formational conglomerates. Evidently the boulders making  
 is near at hand even in the intraformational congl.

Wea.

TUES. JAN. 12, 1909

Ther.

We

Wea.

~~WED. JAN. 13, 1909~~

Ther.

The intraformational conglomerates here can be explained in the regular way — exposure of their li. bottom, sun dried, and then washed up into the angular pieces of li. in a limy shale matrix. This condition can best be seen along the Canadian Nat. R.R. near the St. Joseph ship yards.

But the li. congl. with older li. <sup>thin lens</sup> does not get see how to explain. There are no shore lines here, and therefore no cliffs from which the boulders could have come. Ice-bays could have brought them but there are too many conglomerates to be explained in this way. If the great masses of limestone in the quarry back of Langens are the Canadian in place then <sup>have been</sup> the cliffs from which the boulders came as the sea worked against it.

Could the St. Lawrence geosyncline have been undergoing slight ridding and folding of its bottom during the time of the Beekmantown? If so then all the congl. might be explained as derived from local folding during <sup>the</sup> Beekmantown time. Remember <sup>evenly</sup> the phenomena is local — the congl. occurs all the way from Annapolis to

Big rock cuts to west of Petit Metis, and some to east. Also around Pedoué. All look like Quebec series. Some are red like Killery. It is well covered all about, but by no means mountainous.

All about Lac Seul there, flat land and much swamp. Lake Matapédia to east. Ells says there are Silurian here. Looks like old lake bottom. No rock exposures. Val brilliant is as large as Sagatech or Lajeau; it is beside Lake Matapédia. No rock exposures. Farming and lumbering.

What I saw of the hills I saw with no hills. Small mountains - 600 feet high.

Amqui is another large village at the east end of Lake Matapédia. Hardly any rock exposures are along this flat lake bottom country.

Some good rock cuts to the west of Amqui are at Salmon. Large lumber mill here.

Good rock cuts at Desjardins. Ells calls them Silurian. A few miles east and he calls the strata Devonian.

sketches of the succession.

In the afternoon upped my nest  
of yesterday, and read Walter Las  
Bessy John & H. Stamboldy.

A fine sunny cool day.

Aug 18 - 28 worked the whole  
Pat Daniel area and placed the in-  
formation gleaned in the old note book  
and on the map.

Left Thursday Aug. 28 at  
5:40 on Saco rd. where I will  
be for a week.

August 29, Friday

Worked the shore of Ansea la Vieille

August 30, Saturday

Worked the R.R. cuts at Ansea la  
Vieille.

Wea.

SUN. JAN. 24, 1909

Ther

August 31. Sunday.

As the tide was low walked the entire shore from Point Boleaux, by Chouin and back almost to Anse à la Bielle. The section begins on the Mc Linn's li. and continues down to the Lully li. There made a little headland that we cannot get around. Nearly the whole distance is *Taconurus* shale.

In the afternoon walked the whole shore of Anse Savon and found it all to be *Taconurus*, excepting the two horizons that are of Mc Linn's.

It got cold and cloudy all day and by 4.30 it began to rain.

Wea. ~~MON. JAN. 25, 1909~~ Ther.

Sep. 1. Monday

Took a pill yesterday morning to loose up my bowels, and from my rheumatic condition and the wind had a bad night. It is still raining this morning, cold and nasty and so stay indoors some or less so.

In the afternoon walked around a little but too rheumatic to get about much. Later went out again to the lake to get samples.

Sep. 2-1909 Tuesday

A small drizzle and fall rain showers. Took lunch and collected birds all day on Riddick Point Range. Got a big lot of hawk eggs from four different colonies.

Sep. 3-1924 Wednesday

Spent most of the day about base on  
La Barge to find the fault, and may  
be I found it, but it now seems to  
be unnecessary to have me. I think  
all can be explained through folding and  
steepening and flattening of the beds.

Late in the afternoon collected  
another large set of tracks, out of the  
fourth assemblage in the local li.

Sep. 4-1924 Thursday

Packed up two boxes of specimens and  
left Sasong at 10:15 for Park of Sanil.  
The Baskin tons at Sanil. home stayed  
cheap, too little. Paid for it \$1.25 per  
day. I gave them \$1.00 and feel a small  
bit bit poor man.

Back again at the Ince' was home.

Wea. WED. JAN. 27, 1909 Ther.

Sep 5-1924 Friday

In the morning looked around a little about Port Moresby and the fishing on the reef. Got a few fish.

In the afternoon collected again at the S.W. corner of Port Moresby. Got some interesting fossils and a fine *Brontozoa* tail.

Sep. 6-1924 Saturday.

It is mainly hard and looks like an all day rain. Staid up in the afternoon.

Padded in boxes all my fossils, three good sized ones from about Port Moresby and 2 about 5 cm. ones. I now have a fair collection from this situation, but by no means a good one. That will take your eyes and a full summer to do.

~~Wea. THUR. JAN. 28, 1909 Ther.~~

September 7 - 1924 Sunday.

September 8 - 1924 Monday.

Spent the day crawling east to Barbe and back on the King Road to prove the fault line on my map. Hall agrees my view. Then too I sketched in the distribution of the formations in the wide Mc Simmis syncline. I am sure now that I have the stratigraphic and map of the Silurian of the Pat. David-Basens area in good order.

The thickness of the Silurian is over 5000 feet.

Shipped by Express collect 5 boxes of fossils. They weigh 310 pounds. These with what I had before makes a good representative lot, but in no means the whole fauna. This can be had up by a young man who will put in an entire summer. A good deal of collecting should be done in the limestone to the north of King Road in the Mc Simmis Cove. That is all the other places where Pith li. is exposed, the best place would be Reddish Point.

Wea. ~~FRI. JAN. 29, 1909~~ Ther.

September 8 - 1904. Monday

Shipped my fire boxes, took a receipt and left Port Jervis at 11.15 A.M. Left the train at Cross Point, then by auto to the Postigoche Ferry across the river to Campbellton. Here I stopped at the new Postigoche Hotel over night. A fair looking and good hotel for the place.

September 9 - 1904. Tuesday.

Had a hair cut and then got ready to take the train for New Glasgow and arrived at 10.40 P.M. I left at 11 A.M. Sent Sam a telegram that I would see him tomorrow morning at 9 A.M.

Got to New Glasgow on time at 10.45 P.M. Put up again at the Vendome Hotel.

September 10 - 1924 Wednesday.

Got the telephone & telephone for  
me to Mr. E. R. Chisholm to see about  
Dr. G. Bell. I then found out that he is  
at Westville, and he will telephone him  
there.

Bell met me at 9 A.M. and soon  
we were started to the Virginia coast, to  
see the section of the Coast, west of the Virginia  
line. It is about 50 miles N.E. of New Glasgow.

Started down the Chesapeake in the red  
Knogdact formation. In all probability, all of  
it is terminal Liburian and not at all <sup>as is more often assumed</sup> Devonian.  
Of course then the Learns did not see an inter-  
nal contact <sup>(Liburian)</sup> 200 feet between the <sup>(Liburian)</sup> Strachan and  
the Knogdact, but even so I think the evi-  
dence is best for regarding it as a lower Lib.

The Knogdact is a <sup>thin</sup> shaly sandstone  
slate and muddy sandstone series with short irregular  
bands of calciche. The <sup>Knogdact</sup> <sup>series</sup> continues down the  
stream from the road and near the mouth  
of the Brook in the stream bed is a limited

All much con bedded, and deposition not irregular. Clear a deposit of a desert with all the pebbles <sup>thriftly</sup> coated with iron encrustation.

Also many zones of clay balls, or clay galls. <sup>with the clear diff. from coarse more results of size in the part</sup>  
Above the conglomeration of the upper portion the deposition becomes more regular bedded and becomes more and more a sandstone series.

These are all rippled (cross-rippled) and towards the top, here got Estheria dawsoni.

The whole of the Horton here is about 700 feet or thick. In the cleaner sandstone there is considerable drifted and broken up woody plant material, many which are fragments of Ancinmites. Some of the wood is coral around which are effen deposits.

The Horton is thought to be in broken relation <sup>(disconformity)</sup> with the Windsor since it is at the least Middle Windsor that begins their formation <sup>the evidence do not in the least show of breaks</sup>.

The Windsor begins with about 5 feet of shale with li. zones, and then a li. oolitic thal zone, about 30 feet thick. At the base occur about 10 species of Windsor fossils. The whole of the Windsor maybe 700' thick.

Wea. TUES. FEB. 2, 1909 Ther.

The Windsor orlite is much ruffled, the  
crack 8 to 10 inches apart. In the hollows of these  
ruffles in a dense <sup>non-solifitic</sup> li. occurs *poros bivalves*  
in great abundance.

Over the li. comes about 2 feet of shale,  
and then 10 feet of even bedded, fairly clean  
green sandstone.

Then follows a long series of reddish shales  
and sandstone, the latter all much ruffled.  
Now ~~small~~ <sup>small</sup> ~~wood~~ <sup>wood</sup> fragments are present, but  
no recognizable plants. No *Ammonoites* were seen.

About 500 feet above the base is a thin zone  
of <sup>marly</sup> orlite that has small *bivalves* and a  
*Patellatium*. The *bivalves* look most like  
*Schizodus* but none are more than 1/2 inch long.

All of the Windsor other than the marine  
fossil bearing beds are of desert deposits, though  
one sees here no gypsum. *Schiz* are present  
<sup>however</sup> in thick beds to the south along the Railway.  
The whole is a series of brick red clays and  
sandstones, much ruffled, though actual *Schiz*-  
cracking was not seen. Caliche gorges are  
not rare.

then without ~~break~~ and without positive evidence <sup>for break</sup> comes in a <sup>for 2 miles at base of</sup> layer sequence of Pennsylvanian - at least 2000 feet <sup>(about 1500)</sup>. The only recognizable fossils are Calamites. It is observed sh. and 10. with zones of intraformational conglomerates. These are the Caliche conglomerates.

Bell says that between the Windsor and the Pennsylvanian <sup>= Caliche</sup> there is elsewhere a still older Penn. <sup>= Caliche</sup> series. However on the whole correlations are not altogether certain, but Bell is doing the best he can on all the evidence available.

All the strata seen today appear to be connected with desert conditions - most decidedly with the Horton. No marine horizon is known in our Nova Scotia above the one above mentioned above the regular Windsor one (the one near Pottery Point).

One examination stopped at the mouth of Knopdash Brook, and Knopdash Point.

Doubtful the one regular in conformity today. All is conformable sequence.

Wea. THUR. FEB. 4, 1909 Ther.

The Priest (an Irishman) at Arisaj is much interested in geology, and is inclined to put up in his home the geologists. His name is Father Rankin.

Bell put me up in Norfolk House, a better one than the Pendone.

Last year Father Rankin read in my text-book and said it was "rank heresy!"

Feb 11-1904 Thursday

into East River

In the morning went to west end of Bellston to see an angular unconformity in the Pennsylvanian. It is about as this

This is the most marked Pennsylvanian movement, and after this time came the local deposition.

In the afternoon went north to Middle Row to see the Glasgow conglomerate overlapping the older folded Alma series. In places there is a fault

Wea.

SAT. FEB. 6, 1909

Ther.

At Fort Starn saw the New Glasgow  
 congl. layer made up of granitic material, pink  
 granite, and white orthoclase granite. This  
 granitic debris comes last from Coteguid Mt  
 and overlaps farthest into the basin. The granite  
 was ~~cut~~ <sup>cut</sup> by the <sup>old Paleozoic</sup> <sup>sediments</sup>.  
 I traveled via <sup>the</sup> <sup>old</sup> <sup>road</sup> <sup>from</sup> <sup>New</sup> <sup>Glas-</sup>  
 gow to Westville, and soon <sup>farther</sup> <sup>now</sup> saw a high hill  
 made of the New Glasgow <sup>conglomerate</sup>. Then  
 into Pictou where we looked up the house in  
 which Sir William Dawson was born. A double  
 two story square, <sup>and for looking</sup> <sup>house</sup>, built out to the  
 pavement on Church st. at the corner of George.  
 Dawson could not have had far out of any par-  
 ticular standing, certainly of no wealth. Then  
 two blocks further down Church st. saw the  
 Academy where Dawson got some of his edu-  
 cation. It was the castle school.

Then out to the Ferry River also along  
 Northumberland and to Black Horse, the River John  
 when we had lunch.

Then went up the west bank of River John  
 to see the congl. overlap of the New Glasgow  
 congl. over the older granitic conglomerate.

It is a series of red beds upon red beds  
about as follows:

In this great band we came upon a peculiar  
li. in the Silurian series that projects some into the  
Lower granitic Cryl. Have two pieces. Note the  
almond - Cryptogon like character of the frag-  
ments li. The one must be fairly thick. One  
measured 3 feet thick. Here also I collected  
two pieces and some fossils of the outlying inter-  
formational conglomerate.

Then went up the Hought River to its Falls  
to see the remarkable gorge in the very thick  
conglomerate of basaltic debris. This series  
appears like brown wood 3 feet thick. A mass  
of angular debris, unsorted and of all sizes  
up to 3 feet across. Also many Silurian  
pebbles full of fossils. These are from the Cobequid.  
Stopping at the Logy road, New Patten-  
on, at Tatamagouche.

MON. FEB. 8, 1909

Ther.

Sep. 13-1926. Saturday.

In the morning went to the Malaga Jack Salt Mine in the Windsor formation. Here along the shore is seen a fine overlap of the Picton formation on the Lismore. The former one was folded and overturned greatly and eroded before the Picton cngl. and so was laid down on the irregular surface. Beneath the Lismore is the Windsor of which one sees a little gypsum and dolomite. Near by is the Salt Mine beneath the drift. The drift is salt in some places - they speak of two hundred feet.

The Lismore has many bands of Saline cngl. In these <sup>is</sup> has been left to be preserved of Cordaites logs. The outer layer is coal and the inner part is replaced with lime preserving some of the structure.

In the Picton of Malaga Jack Point there are three beds of li. wide, separated. They vary from one to three feet thick, and one of peculiar blue color and irregular deposition, a lumpy sort of deposition. Beneath them and especially one of them

Wea.

TUES. FEB. 9, 1909

Ther.

is a soil bed - now red clay with *Stigmaria* which  
<sup>an</sup> was transported into this state. Beneath the  
*Stigmaria* the red clay is full of green fillings  
of the *Stigmaria* roots. It is the lime that  
has preserved the *Stigmaria*. Therefore one  
sees the outlets of *Stigmaria* without the *Stig-*  
*maria* themselves! These li. must be lake  
deposits, dust blew into them, and the li. pre-  
cipitates probably through algal or other plant growth.  
I have a piece, and it ought to be studied  
physically and chemically, because of its desert  
character. The thickness of the beds was regular  
across the beach - several hundred feet across - and  
flat topped. Evidently the lakes had considerable  
extent, but shallow and at first a swamp of lycopods.

On the beach slopes, at low tide, on sand  
bottom one sees a sort of current ripple, the crests  
of which are all truncated. These flat tops may be  
 $\frac{1}{4}$  inch up to  $\frac{1}{2}$  inch across. The ripple hollows  
are acute and often deeper than usual. This type  
of ripple is also seen in these Pennsylvanian  
deposits. So, an indicative of very shallow water  
over which the wind is blowing, and flowing.

Wea.

WED. FEB. 10, 1909

Ther.

There is an extraordinary amount of ripples and often even ripples in the sandstone of the Pennsylvania, in fact every sandstone bed is rippled and even bedded. Sometimes the sandstone predominates, and then the red shales, and then again there is an equal amount of both. The shales as a rule are all pink to brick <sup>red</sup> and it is rare to see green shales. At least one such green was seen today in the system, and it had one species of Plectambonites well preserved and common.

Nevertheless the same evidence is of corals and Cordaites leaves in the sandstone. When the Caliche conglomerate are present there may be preserved an abundance of Cordaites wood. One fine trunk was seen in the Lismine today near the Malabar Salt Mine.

Some crinoid and rain prints were not seen or at least none, but much of my inspection was too dark to note them.

Wea.

THUR. FEB. 11, 1909

Ther.

The evidence appears to be conclusive that desert conditions appeared with the late Silurian and then continued through the rest of the Paleozoic. Desert conditions are most marked in the Boston, Windsor and later Pennsylvanian. It was probably the rising of the Canadian geosyncline into mountains that brought the Desert climate, and then it continued here certainly to the close of the Triassic. Of later times we have no records here.

As the Nova Scotia coast opposite Prince Edward Island is all of red Pennsylvanian, and on the cliffs are low and seemingly in one or more foldings, it is reasonable to assume that much of the island is of Pictou Pennsylvanian. Some oil was set back a box of limestone from the island and these are of Windsor time. Therefore there appears to be late Windsor overlain by Leaside and Pictou. Now then, is there any Permian here? Bell says Osulchis is reported from Prince Edward Island. There might be no Permian here, but rather the Leaside of Pennsylvanian, above the Westphalian. Look up Case on Permian reptiles.

Feb. 14 - 1909. Sunday.

It rained hard last night all the morning in  
dawn. The day cleared into a beautiful warm one.

At 9.15 we motored to Mrs. Glasgow and got  
here at 12. The distance was about 60 miles.

All in all I motored with Belle during the  
past 5 days more than 300 miles.

Had dinner and supper at the Chickadee.

Put up again at the Prospect. Will get up  
at 3 A.M. to take the train for Gosport.

Feb. 15 - 1909. Monday.

At the depot found out that no steamer  
for Boston on Monday. Then concluded to go  
via rail (Norfolk, Pitt John, Newburgh and  
Portland) to Boston. Will arrive tomorrow  
morning at 8.

This man maybe as thick as 20 feet, and the various lentils hereabouts vary from 10 feet across to about 200 feet across.

Saturday  
St. Albans, Vt., Sep. 22 1928.

Started south to Georgia township to see the ls lentils near the base of the Highgate to the N-E and west of the little R. <sup>in the narrow gorge</sup> on the topographic sheet of St. Albans. These were discovered last year by Keith but I had seen <sup>some of</sup> them with Horrell.

The first one seen <sup>is</sup> a large one about 140' x 120', and at least 10' thick. <sup>It is made from rough and matrix R.</sup> The reef is growing quicker than the Highgate sh. The whole ls is probably of algal growth <sup>but</sup> unlike Cryptogran. Took a number of pieces to see if they would show algal growth. They seem to grow in vertical main principal nodes to about 18 inches in diameter and weather in three patches that lie in fissures surrounded by yellow weathered argillitic stuff. The whole surface has a wavy appearance <sup>(probably due to weathering)</sup> with the cracks usually 6 to 10 inches apart, but sometimes 18 inches. Keith has pictures of them and close up views of the vertical structure. Saw no fossils here.

Then crossed the E.W. private road to other ls lentils <sup>to the</sup> south and to the west of little R.

Wea.

SUN. FEB. 21, 1909

Ther.

The fossils gotten in these lenses will prove the age. There should be many new things. All are trilobites - one sees nothing else. They lived about the reef and where concentrated and deposited in the hollows of the reef. The lime must have come from algal growth almost wholly, but the many trilobites indicates the presence of other animals for them to feed on.

Wea.

MON. FEB. 22, 1909

Ther.

on the topographic maps. Here there are three <sup>lentils</sup> ~~clays~~ together. One 18 x 10 ft across had trilobites in at least two places and probably many more places. One must <sup>find</sup> these pockets, and among near much calcite that appears to have kept the ls from undergoing diagenetic change. Clark found the first place, a spot about four inches across, and then Keith got one such place about 18 miles long. This I then dug up and took most of it. Has fair trilobites, <sup>one with thorax,</sup> and several appear to be Paradoxides. If or it will upset Keith's mapping. Probably, however, it is known Stiphodon.

In the shales close by Charles and Mc Berigle found <sup>two</sup> small trilobites in the Stiphodon or adjacent shales. I have the two specimens.

Another lentil is 18 x 10 ft and here Clark got one or two trilobite fragments that I

<sup>have</sup> close <sup>by</sup> is a much larger lentil surrounded by shale. But no fossils here.

Close by these lentils in a shale outcrop Mc Berigle got a loose ls boulder weighing 50 pounds with many trilobites. I took away <sup>one</sup> ~~one~~

Wea.

TUES. FEB. 23, 1909

Ther.

Later this loose piece turned out to be Stanton congl. Therefore it is far out of place. The fossils were broken out at home and would be found in the 1928 collection.

Reith has contoured this reef on his maps. He has also located the other reefs, I saw at least five of these reefs, but knew one more.

Wea.

WED. FEB. 24, 1909

Ther.

of this mass. Keith said it undoubtedly was a piece of one of the lentils, and this I can prove by the fossils actually collected from the first smaller lentils. See opposite.

Then went further south to see the largest lentils of all. This one rises abruptly out of the shore, probably 20 feet high and something like 200 feet across north and south and east and west. It has many trees growing on it. We made no attempt to collect fossils.

Those <sup>are</sup> all the lentils known in situ. Rockledge to the north of St. Albans may be another <sup>one in place.</sup> The big boulder in the Swanton cove, to the south about 1/2 mile, is a boulder lying in the main of the <sup>It is a transported mass</sup> cove. Here we ~~see~~ saw what looks like reef structure with here and there a piling <sup>as in the lentils to the south.</sup> in small places.

In the afternoon went north to Highgate to see the *Meriostoma*. Last year's flood has cleaned up the basal strata, and now one can make <sup>out</sup> a complete section and <sup>gather</sup> a more detailed collection of fossils. This I will do in a day or two later.

St. Albans, Sunday, Feb. 23 1928

It is raining this morning, and we are kept at the Tabern.

In talking over the section of St. Vt. with Keith he is thinking of changing some of the formation names. Coldwater at the type loc. is without fossils and now he will use Parker from "Parker Cobble" the local name for the prominent high hills known to the neighborhood. <sup>in the region</sup> There is where Halcott got his famous Parkers Quarry Lower Cambrian fossils.

Swanton congl. was taken from Swanton township and was once much used for Swanton marble; also there is more than one congl. in the township, hence he now prefers to call it Sheels from Sheel's Corner. This congl. lies in the mid-length of the congl. at the base of the Burgis slates = Red mountain.

High grade sh. is to be restricted to the top. Sh. that in places must be 1000 feet thick. It has no ls., all bedded slates. Takes down to the base of the granitic gneiss etc.

Sunday Sep. 23-1928

By noon it cleared up and we conclude to go to Canada with Clark, McHugh and Erickson. They had first to repair their car and it was nearly four o'clock by the time we started.

We go via Greens Corner to the northeast and finally near Richmond cross over into Canada. Got to Lethbridge seven miles north of the boundary, at 7 P. M. We traveled 35 miles and looked at some exposures of the Algonkian series, and then some Highgate, and more Algonkian.

It is getting cold.

The Pre-Cambrian is mainly gneiss, but here are zones of quartzite, schist, and diorite. In Canada it has chlorite schist = metamorphosed igneous material - lavas and tuffs. These occurrences do not occur in Wt.

Wea. FRI, MARCH 5, 1909 Ther.

Wea.

~~SAT MARCH 6, 1909~~

Ther.

Montreal Sep. 24-1928  
Sutton, Quebec.

Slow in getting started because Claude's car is out of order.

Looked at Algonkian series to east of Pinnacle Mountain. Mostly greywackes with zones of quartzite, iron pebbles and schist. One zone of sandy dolomite on each side of a syncline, about 100 feet or more thick.

The thick zones of quartzite look like dome deposit because of the cross bedding that in places is distinctly concavely bedded.

Also saw zones of chlorite schists, all metamorphosed lavas and ash beds. Amygdalites large and common.

Evidently the Algonkian series is made up of marine dolomites, land lava flows, and continental dome and water laid sandstone zones of ash beds and iron pebbles.

Back to Sutton for lunch.

Then started for Qull Hill near Cowansville, to see the lowest Paleozoic series. On the top of the hill is a thick bedded white quartzite

Wea.

that Keith says looks like Choshio = basal Lower Cambrian, top of a thrust sheet.

Farther down lies a zone of dolomite that looks <sup>like</sup> those we saw this morning. If so it maybe of another thrust sheet.

Still farther down lies a thick mass of banded slate grey, much like the Hightgate and which Keith thinks may be of his time. Saw no fossils.

At Covansville we descended into the formation a River to see the steeply standing slate with a few zones of limestone. In the shale Keith collected a *Bryozoa*, and he says we got a *Plectambonites sericeus* and a few other fragments that we could not determine.

Then went to near Fordyce Corners to see blue-black slates with large specimens of *Chimnapptus*. I saw a piece.

Then autoed to Phillipstown where we put up for the night.

Reith says this is probably the first area anywhere N. of the N.Y. Highlands to see a dissected overthrust sheet and its basal mylonite zone.

I think Clark had interpreted it as a conglomerate zone, and that he had no idea of its being a thrust plane. In many places we could see the contact of the Mallett on the Beekmantown. Usually the contact was high angled - say 30° to 45° but up on the whole the thrust plane appeared to be as low as 10° or less.

Wea. ~~WED. MARCH 10, 1909~~ Ther.

Tuesday, Sep. 25 - 1928.

Started out with Clark, Crickey and  
Mc Kerrigle and the Keith's from Phillipston,  
to the N.E. towards Bedford.

First stop just north of Grove Hill Farm of  
W.C. Brown, 1 1/2 m. N. of St. Armand. Here  
one sees to W. regular Beedmantam with  
fossils. To the east of it is Mallett an overthrust  
sheet pushed to the east over the Beedmantam.  
At and near the junction of the two formations  
one sees much oncolite and to E the middle  
member of the Mallett that here or elsewhere is  
marked by interbedded retrosus quartz. The latter  
is usually near the base of the Mallett and evi-  
dently is secondary after the overthrusting.

The Beed. is locally much faulted and the  
blocks offset with little throws of two feet or so. The  
faulting is due to the unredding and thrusting Mallett.  
In places the Beed. blocks are much pushed  
around and out of place.

I got the idea of a great development of Beed.  
followed by the Chazy ls and dol. The latter is

Wea. THUR. MARCH 11, 1909 Ther.

Wea. FRI. MARCH 12, 1909 Ther.

Tuesday Sep. 25-1928

Best seen about Rosentey school about four miles south of west of Bedford. In one zone especially fossils are exceedingly common, and never have I seen so many in one bed before. All are suggestive of Chazy species, since I saw no Piloceras or coiled forms, and all have the septae far apart. Just east of the school is a thin zone with trilobites of which I saw no good specimens. Here I saw two forms of a Camarella, one elongate the other deeply sulcate, and a fragment of what looked like Rhynchotrema plena. Saw Cameroceus, Orthoceras, Querecias and Dawsonoceras. Also large and very thick Maclurea, large enough to be M. magna.

In the river in the town of Bedford there is exposed a thick ~~so~~ congl. series at the top of which is a sh. series. Saw no fossils made it clear report any. It looks like a younger series than even the Chazy.

Wea. SAT. MARCH 13, 1909 Ther.

Wea. SUN. MARCH 14, 1909 Ther.

Tuesday, Sep. 25 - 1928

Just south of the R.R. station Mystic there is a little bit of a limestone conglom. The pebbles are usually very small and of a dove colored ls. Saw fragments of fossils but got none that could be determined. What the Ord. age is one could not determine.

In the shale beneath the little bridge just south of the Station Clark found an Isopropites. Clark says it is close to Didymopapirus caduceus. This appears to indicate the shale phase of the higher Beekmantown. If so the ls. congl. maybe the basal zone of the Onondagian sh zone above.

At by S in a straight line about  $\frac{1}{2}$  mile ~~and~~ of the Mystic Station occurs apparently the same ls. congl. as the one mentioned above. Here One Serrill had collected many fossils - Llogdia not common and large, clearly indicative of the Beek. Other fossils are Leperditia and Plectothis. Evidently a mixture of Beek. and younger fossils, but the exact age of the congl.

Wea. MON. MARCH 15, 1909 Ther.

Thurs. ~~Wea.~~ TUES. MARCH 16, 1909 ~~Ther.~~

Tuesday Sep. 25 - 1928

is unknown. This congl. appears to be surrounded by shales.

The place where Raymond and I collected some years ago in a congl. having Romplexites is two miles north of Bedford on the east side of the road. It is about  $\frac{1}{2}$  mile in on a private road to what was once a quarry here. I remember seeing here much Beechmantle in place. We did not stop here today.

Three miles to north of Bedford in the fields along to north of road occur thin ls lentils in a block of sh. Here we saw Plectambonites sericeus and smaller thin flat Rafinesquina alternata; striae equal and bundled. Evidence of this is the Trenton series of shales.

Clark told me that the Laugm ss near Quebec are interbedded in the red Lillery sh, and that all of these strata may be of non-marine origin. He thinks the Lillery goes unbroken into the Levin sh, congl. and local ls, and that the

Wea. WED. MARCH 17, 1909 Ther.

Wea. THUR. MARCH 25, 1909 Ther.

Wea. FRI. MARCH 26, 1909 Ther.

Wednesday Sep. 26 - 1928

All of the Minisquiri and Milton dol. are very irregular in deposition swelling thick and thin. They give the impression of being reef formations and of local origin and must accordingly be very variable in appearance and in thickness.

The quartzites are even more irregular, and appear to be sand bands of local current action, in and out of the section. The greater thickness of the quartzites will vanish away on either side in from 100 to 300 feet.

The Haed dol. sh. appear to be more persistent and especially in the upper part of the series. Such beds must originally have been present throughout Milton time since these beds were broken up and the angular pieces embedded in the dol., the characteristic feature of the Milton and which (Haed) inclusions distinguishes the Milton from the Mallett. The latter has also inclusions but these are not Haed.

Wea. SAT. MARCH 27, 1909 Ther.

Wea. SUN. MARCH 28, 1909 Ther.

Wednesday, Sep. 26, 1928

This morning in going directly south from Phillipstown, Quebec to Highgate Springs we are all the way on the Marble bed of the Beekmantown. It continues on south to at least the Fond du Lac south of Oranoutan, that I formerly thought might be Chazy.

A good place to study these ls and the great outburst just to E would be to make a base at the Franklin House at Highgate Springs. To the east is the outburst mass of Mallett that I once assumed with Deceatur. Just east of Highgate Springs is a small lime quarry in this Marble zone. Farther east this Marble bed is repeated according to Keith. Then comes the Mallett with the zones of the Parker or Colchester sh. Finally the Milton and the Minisquir.

Got to St. Albans at 6 P. M. and put up again at The Tavern.

Wea. MON. MARCH 29, 1909 Ther.

~~Wea. TUES. MARCH 30, 1909 Ther.~~

Thursday, Sep. 27 - 1928

Daid morning and rain. Cleared of later on. Left St. Albans at 10 A. M. for Williston where we lunched.

Then back to Burlington to call on Prof. Perkins who is still teaching (60 years of teaching) at the age of 84 years and does not wear eye glasses.

Then on to Rutland. The Green Mts had their first evening of snow, and it rained off and on while going through the Mts down the Black River.

Put up at the Grand Hotel at Burlington. Professor Emeritus Breckenridge was here for the night, and in the morning goes to his summer home at Mount Philo.

July 16 - 20,  
1932.

Wea. Mon ~~APRIL 5, 1932~~ Ther.

New Haven, July 16 - 1932  
Saturday

Longwell had lunch with me at the Graduate Club and at 7:45 A.M. we start for North Kenton and soon to go to northern Vt. At 8:15 we are off for the north on a perfect day.

Near Becket Mom. we stop to see Longwells little daughter, and then we proceed north. Had lunch at the Rose Restaurant in Pittsfield.

We go north by a route I saw once before, with Raymond, via Bennington and Franceville to Rutland, Vergennes, and Burlington where we arrived at 7 P.M. Put up at the Danmore Hotel run by the Vermont Hotel Co. in the opposite corner.

With a cloud in the sky we had fine views of the Adirondacks and the Green Mt. range. Heavy stand out pine. The country is green and shows a great abundance of flowers, especially rambling roses.

[loc D2352]

Took away a large quantity of the Lingulepis.  
These del. Lingulepis beds to be at least 150'  
thick. ~~The beds are thin and shaly and are~~

The entire del. is now a low ridge, with beds  
decidedly sandy, and then goes up to about 100'  
thick, then is greenish and up in the series.

The sand is very fine and appears to  
be wind blown. These del. must have formed near  
a shore.

Later on it may seem that the change of dip  
is due to a flexure. According to the Lingulepis is  
in the lower part of the 150', but beneath the  
top of it is even lower, about 100'.

Eastern part  
of 150-200'

Western part

Wea.

~~FRI. APRIL 9, 1909~~

Ther.

We next returned to Ulysses, i.e. No. 2 and No. 1. We searched three hours and found no *Heldrin* layers present. That was a mistake. We searched a well which would have been hit.

The dol. here is again a blue gray thin bedded dol. much torn and filled with quartz filling <sup>or reefs</sup> the surface weathering into a very irregular surface. <sup>or reefs</sup> surface was a less regular with sharp. It was a <sup>small</sup> <sup>little</sup> <sup>of</sup> <sup>interpenetration</sup> of that weathered out as beds. Saw a little Cratogeomys.

A little farther N.E. of No. 2 about a pond a Chambella bed was seen, and we saw a bed of a trilobites and another red bed. Got a Cratogeomys. All are of the Cratogeomys type.

The bed is yellowish reddish weathering thick bedded massive. It dips 40° to the E. and is of highly variable date.

The Highgate stone is very little and extends over a long distance. It planes to slate in a little bit into the west and is bedded 30°; trends to the west and is the oldest lies to 700 E. The Highgate appears to be the usual type but this may be due to quartz filling.

SUN. APRIL 11, 1909

Ther.

It is not certain that Ulrich is in error in saying that the conglomerate here, making the "Milton dol." having Westphalian fossils. How he came to make this error is hard to say. I must see the fossils.

It is also certain that the "Milton" is of Upper Cambrian age. (See Logan's report). Can't Ulrich show what fossils he got here.

He did not report the fossils, on account of the rocks.

After some rain and a halt, we returned to Milton to see what he had originally said. Milton dol. is, in all respects, the same as the dol. in the Westphalian sequence equivalent to the Rutland dol. We looked at it at Milton and found it a much washed and rather shaly dol. with the same fossils as the Westphalian sequence.

It is now plain that the Westphalian sequence at Milton and that the Milton dol. of Logan are Upper Cambrian and the equivalent of the Middle Devonian. The Westphalian dol. and the Rutland dol. are both Westphalian.

Wea.

FRI. APRIL 23, 1909

Ther.

In the Adams's structure the cgl. at base of the Highgate is a brecciated mass of older ls. lentils. Here we see <sup>almost</sup> none of the stately Missisquoi ls. In the Skeels corner cgl. the lense is lentil blocks are very large at times. Up to 20' diam. The cement is a sandy <sup>sil.</sup> one, and in places, true in a matrix of gt.

The Mid. E. of Adams are of a greenish gray coarse material that is decaying in places. It is more rounded than or black as the Highgate. If Adams sit south to the east of the cgl. the lense is a very blue place. They are still in some places.

The gt (ortho) are interbedded in basal part of the cgl. Adams sit minute brachiopods and other fossils. The lentils are up to 3" thick. They show the same cgl. matrix about 10' to the S.E.

The Mid. E. since masses to be seen in the cgl. are out of place. They have the same form as the Adams. That they are out of place is shown by the fact that they are out of place. Keeping with that of the cgl.

Wea.

Tuesday, July 19, 1937

Wea.

~~SUN. APRIL 25, 1909~~

Ther.

2000' at top of the Colchester sh. place and forms on the St Albans Bay road west. Here the Colchester sh. with thin dol. beds is overlain by 20' of massive grey dol. Here I once saw a piece of black sh. overlain by the heavy bedded dol. It is three-quarters of a mile back to the Adams Pasture to east. As the massive bedded dol. dips 11° S.E. and the Adams Pasture  $\approx 70^\circ$  the average dip is  $10^\circ$  to give out the thickness. The distance is 1585' at  $10^\circ$ . Thickness of Adams sh. is 274 feet.

Being south on the road to Mill Hill it seems much of the upper Colchester sandy dol. in mass is like these weathered shales. Here they are the cliffs up to 30' thick. Here the sh. is a 10' or more thick in some places and the whole weathered sh. into an  $\approx 10'$  thick sandstone. Beneath this is the regular  $\approx 10'$  shales with nodular layers that weather into a shaly powder. But I could not find any fossils. These shales are richer in mica, the same layers and more conspicuous than the Colchester sh. Here they are  $\approx 10'$  thick. On my way I called these Mallett and then changed it to Mallett.

Wea. MON. APRIL 26, 1909 Ther.

On the long art trip found that Rupp took cyl. to  
be at the base, the old bitoum, while the newly  
Mill River is at the top, and on the character of the  
cyl. in the bed of the Pasture.

Tuesday July 19, 1932

Wea. ~~TUES. APRIL 27, 1909~~ Ther.

Then continued with me into the Conroy  
Mid. C. place. Here we saw about 15' more of  
the same dol. as before interbedded with sh.  
Just what the age of these beds is not known, but  
for the present are here recorded as L. C.

Further south is a 100' cgl. some of which is 10'-15'  
to 2' with pieces up to 2' across. It is sandy dol. cgl.  
Over it follows about 100' of a level shale  
more or less of which is the lower part of  
C. C.

The distance from the basal cgl. to the level of  
Adams sh. is about 150 yards or more. It is about  
100'

The top of Adams sh. is about 100'

When the road passes by the cgl. & immedi-  
ately to the east of it we see the same sandy dol.  
cgl. as at the Conroy place. Here it is at the base of the  
St. Albans, about 10'. Is this Adams sh. or is it cgl.?  
If so it cannot be correlated with the Adams  
parture at the top of the St. Albans sh. as the lower  
cgl. has pieces of the same sandy dol. of the L. C. and  
one piece about 2' in diameter. The St. Albans sh.  
is here more or less continuous.

Wea.

WED. APRIL 28, 1909

Parker's Cobble is in two hills. Tralcott's  
quarry is at the base of the western hill. The eastern one  
shows the 30° of capping dol.

As the dip <sup>of the next dol.</sup> is to the north the first one described  
is at the higher level, the second <sup>is in the hill</sup> is lower and  
departs by about 10 to 15 feet of grade.

Tuesday, July 19, 1932

Wea. THUR. APRIL 29, 1909 Ther.

Then tried to find the epl. to equivalent of the Adams Padam one, to the east of Ruggs' Brook but found none. Saw several other exposures between approach to the high gate sh. In looking west to Ruggs Brook saw one exposure. Decid. for rocks appear to me if he has such a high a shale just out on my map.

Found another thin bedded zone (p. 6 to us) while hunting in the above epl. It is probably in the <sup>lower</sup> high gate but may be in the sh. at bottom sh.

Parkers Little. Looked in the lowest quarry at the base of the hill, and even Carl. W. Deane has had two very specimens of atypical bedding.

In the midst of the shale on the most westerly here occur two grey dol. lenses that weather a rusty yellow. The lower one is 10' long and about 11 in. thick. The higher one is about 50' long but is 8' thick. Both entirely in the shale between than 30' beneath the capping thin bedded dol. Compare with Walesito section. It is a blue-grey dol. weathering white lit.

Rock Hill is a land interval  
 and because a disconformity between the  
 Lower Cambrian. It is not the hill it was  
 supposed to be, but now we see it was  
 different. The Cambrian dol. were laid  
 down. The bed or these upper dol. should  
 be variable in thickness from place to place.  
 At Parkers Hill it is 30' thick, but one mile  
 south of same distance it is over 100'  
 thick. I don't need to say that the 'Milton'  
 varies from 0-500' Evidently their greater  
 thickness is on the west.

Tuesday July 19, 1932

Wea.

~~SAT. MAY 1, 1909~~

Ther.

About  $\frac{1}{2}$  mile south of Parkers Little and a few hundred feet east of the road is a little hill with some very good fossils. It is made of a little bit of higher lime of what is to be the St. Albans zone. The hill has a height of about 100' long. In the center of the hill are two other hills, all of which are in the St. Albans sh. zone, and in many places near 266'. These fossils are chiefly to the east of the hill at the top of the Lower L.

We then started to see the dense masses of the Swain sh. about one mile south of the center. The main mass of the ls. is a part of the lentils, some of the white bridgehead and other are of the light blue type. There is also a considerable flat bedded ls. zone. In other words it is of the Swain sh. zone.

The two areas are separated probably 1000', and in between is a thin bedded grey sh. and at the east end is a little black shale zone. The ls. is high grade. Schistosity is everywhere marked so the appearance is that the Thota

Wea. THUR. MAY 13, 1909 Ther.

East over the top or higher <sup>comes</sup> Mallett, a shale  
wide enough to admit Parker shale. Here on the  
surface next to the Mallett <sup>at west</sup> we see plenty of  
pieces of the Parker shale. Farther east near the  
west N-S. road here is some Mallett like dol.,  
evidencing the Parker <sup>at west</sup> dol. It has about the  
same thickness. <sup>around 30 feet.</sup> It is from 300-400 feet to the N-S.  
road but comes out at the west end of Adams Pasture.

To the west is very well flat land with Adams  
Altans, being the Highgate and Highgate etc.  
Unless some one had the idea of dipping the  
Highgate no one would be able <sup>here</sup> to determine the  
line between the Highgate and the Parker.

At the Adams Pasture about 300 feet west of the  
road several pieces of Adams are found in place.  
The slate looks like the Adams in the Adams  
with traces of large pieces here and there with  
material. It appears to have the same dip  
as the Adams, about nine degrees. (95+90)

The Adams Pasture is a nearly all the Highgate  
white lentil to north of it angular pieces of all sizes up  
to large ones. There is some of the Adams in the Adams

The egg appears to have a greater thickness  
 of from 10 to 12 feet and certainly does not exceed  
 15'. It also appears to be somewhat in re-  
 sponse depth in the position of the center of  
 the lentil in the Id. Illinois? Where it looks like  
 the L.C. lentil yet I do not see what could  
 transport the L.C. lentil to this place. If it was  
 in the Pangea state like that it must have been  
 moved at least 1/4 mile.

The length of the egg from N. to S is hardly more  
 than 300 feet.

There is very nearly a small piece of a very sandy dolomite out of the *Proletaria* or *L. dol.* in the *L. Parcus*.  
Otherwise there are no fossils here. The *Proletaria* in the *Parc*  
ground sand can be identified by the *L. dol.*  
I measured the dip of the sandy layer near the  
east end of the *Proletaria*.

the *Proletaria*

The *Proletaria* immediately above <sup>the *Proletaria*</sup> is a *Proletaria* *Proletaria*  
from the *Proletaria* *Proletaria* *Proletaria* *Proletaria* *Proletaria* *Proletaria*  
dip as  $70^{\circ}$  to  $80^{\circ}$  N. *Proletaria*

One sees no other fossils of *Proletaria* from the  
*Proletaria* *Proletaria* ( $= 90^{\circ} + 0^{\circ}$ ) and the top *Proletaria* of the *Proletaria*  
(*Proletaria* *Proletaria*  $50^{\circ}$ ). The sandy *Proletaria* must make  
up  $1/4$  of the *Proletaria* and  $3/4$  is *Proletaria*.

Wea.

WED. MAY 19, 1909

Ther.

A fine cool day after the rain of last evening, but I do not feel like walking and exploring in the State an hour's walk east of the hill back of the village of Altamira. Among fine water and some of the ridges are paved with slabs of pink thin long quartzite and what looks like slabs of the same <sup>but quartzite</sup> reddish brown color. The former show fine translation ripples, in the form of the run of the ridges and three slabs were reflected in rain pittings. These phenomena show unmistakable beach evidence in a very shallow sea.

On the hillside slabs rippling is also common with coordination with some translation ripples. On these slabs whether they are quartzite or not, evidence of translation is lacking. It will not have been much deeper than 20 feet. Here the material must also have been in water, hardly grains of dolomite but a fine sand somewhat of dolomite. However as before showing that the Altamira was a very shallow sea and it may be that no part of it was more than 20 feet.

St. Albans Bee. At the north end of the village  
crust of the Phillipsburg is at the surface and well  
exposed. It is light blue ls. <sup>only dolomite lams</sup> dipping E. 20 degrees. It is about  
20' lower to the lake level in which zone we see  
no outcrops. The Phillipsburg is exposed in the terraces  
and hillsides of this <sup>into the east</sup> locality and somewhat west of here.

From <sup>into the east</sup> here we find (2 or 30') of the same bedded  
Stinsonian dipping  $\frac{1}{2}$  about 90. It has now the same thick-  
ness as seen in the woods farther north. Finally at the E.  
comes in a zone about 20' of Mallett, then about 25'  
more of Stinsonian, and then another <sup>but more</sup> thin  
is corals - Mallett. Their usual top is about 10'.

This Stinsonian-Mallett series has about the  
same thickness as the Stinsonian here.

Farther east is a low ridge of Parker  
shale with a low dip (not more than 10°) that  
takes one to near the Ruff Brook road where  
the upper dolomite of the Parker comes in. This  
Parker probably has the thickness seen in the  
Ruff Brook, namely 200' according to the 1870s.

The basal 25' or so of the Parker is a mas-  
sive <sup>course of</sup> blue granitic ls. with dark locali-  
gations that weather out and leave a blue  
suggesting a cgl. which it is not. In this

It strikes parallel with the R.R. (i.e., N-S.)  
and makes a ridge about  $\frac{1}{8}$  mile long.

Is the metamorphism due to the overthrusting  
or was it done when the entire region was folded?

Sunday June 14-1932

Wea. TUES. MAY 25, 1909 Ther.

A fine cool Sunday morning, and I appear  
to feel better. At 11 A.M. from my room I see  
the Swanton.

After lunch went E. to the "Crazy" exposure beside the  
E-W road to Highgate Center. It is the equivalent Phillipsburg  
series. One alteration is <sup>massive</sup> of granite and dol. that have flown  
massive con into one another. The dip is high from 50°-60°  
or more to the E. The dol. are much torn due to plunges.  
As with the "Crazy" and <sup>massive</sup> of the Phillipsburg marble, but  
other marble bed, with same <sup>massive</sup>.

Just at the N.W. of the <sup>Minisquiridge</sup> <sup>bridge</sup>  
one can see the Phillipsburg <sup>massive</sup> whole marble dipping  
E. about 25° <sup>the dip is about 20° high.</sup> I saw the same marble at the N.  
Minisquiridge bridge in Swanton where all the rocks are  
and no doubt can be seen.

South of the river the banks are made of the <sup>Minisquiridge</sup>  
and grey <sup>conglomerate</sup> dol. <sup>massive</sup> <sup>granite</sup> <sup>etc.</sup> <sup>high</sup> <sup>and</sup> <sup>good</sup>  
dip <sup>to</sup> <sup>the</sup> <sup>W.</sup> <sup>at</sup> <sup>20</sup> <sup>to</sup> <sup>25</sup> <sup>degrees.</sup> <sup>It</sup>  
is <sup>very</sup> <sup>hard</sup> <sup>to</sup> <sup>see</sup> <sup>the</sup> <sup>difference</sup> <sup>between</sup> <sup>the</sup> <sup>quartzite</sup> <sup>and</sup> <sup>the</sup> <sup>grey</sup> <sup>about</sup>  
1/3 mile the <sup>harder</sup> <sup>shale</sup> <sup>comes</sup> <sup>in</sup>, and it can  
be followed <sup>back</sup> <sup>along</sup> <sup>the</sup> <sup>river</sup> <sup>to</sup> <sup>a</sup> <sup>point</sup> <sup>within</sup>  
1/3 mile. <sup>James</sup> <sup>at</sup> <sup>the</sup> <sup>tip</sup> <sup>is</sup> <sup>a</sup> <sup>dol.</sup> <sup>one</sup> <sup>is</sup> <sup>at</sup> <sup>the</sup>  
the <sup>corner</sup> <sup>at</sup> <sup>the</sup> <sup>end</sup> <sup>of</sup> <sup>the</sup> <sup>bridge</sup> <sup>side.</sup> <sup>The</sup>

Initially the ... of the ... have since then is  
 and Parker ... the ... of the ... has Mallett  
 and Parker ... in ... 3 times.

The Mallett ... the ... Parker  
 state have together the ... the Mallett ...  
 around ... It is curious here to see the  
 Parker in between the heads of Mallett. This  
 from here could be ... between the  
 Mallett and Parker as Keith assumes.

Wea.

FRI. MAY 28, 1909

Ther.

The Kenides quarry on the Ironton road, does  
it belong to J. P. Kelley, or J. P. Kellogg (old  
Cushman farm). In Ironton township.

Farm of John P. Rich (an electric road  
used to go through his place. Place for  
fossils, see page Edson (1908).

On the Bullard farm occur two lenticular  
ls "that are particularly rich in fossils".  
Shortly to the north of here ls is more of  
the same rock up to the crest of the idea  
mountain and Lutaquia.

Is the Bullard farm near the Donaldson  
farm? No. It is about opposite the Ford  
Quarry.

East of the Barny quarry (Ironton on north) in  
the Parkers shale occur lenticular masses  
of ls "rich in fossils": *K. cingulata*, *M. festinata*  
*Phidra montanensis*, *Rustella edsoni* and trilobites.

Wea.

SAT. MAY 29, 1909

Ther.

Started on the 10 A.M. Sec. north for the road east side of Swanton Junction east to Rockledge etc. On the higher part of the road about one mile S.E. there is a ledge of Parker's slate. Saw no fossils. D's  $32-35^{\circ}$  N.W. about 700' N. they dip  $15^{\circ}$  S.E., the normal dip.

About  $\frac{1}{4}$  mile farther N. there is a ledge (2 Mallett) dip. in E. about  $13$  to  $15$  degrees. There is about  $15'$  of it and beneath is more Parker's slate dipping to some N.W. It is a blue-gray fine crystalline dol. with some interbedded shaly, almost slate dolomite. Weathered close red.

About  $100'$  farther west is another zone of the same kind of dol. but here it has much coarse sand and in some layers almost a green tuff (2/3 sand and 1/3 dol.). This zone is about  $10'$  thick. Dip  $15^{\circ}$  E as before. Directly beneath this is a gray fine grained sandy dol. of about the same thickness. The dip is more or less east and less than  $10^{\circ}$  E.

Still further in the section (still W) is more shaly dol. and slate with irregular masses of the same blue-gray thick bedded dol. It is all in layers from a few feet to  $30$  to  $40$  feet across. It makes a distinct ridge. The dip across is from E to the west.

Still further W is the broad metal quarry where

Wea.

SUN. MAY 30, 1909

Ther.

The layer for all actinoidites is about 10' above base of the shale quarry. There seem to be 12 arms.

All of these strata dip east about 10°.

There are two or three flint-white d.s. each 10 or more feet thick and weathering down exposed.

Monday August 15-1932

Wea. MON. MAY 31, 1909 Ther.

Left for Oklawaha and Raymond an entire  
Olenites thompsoni. There is some of Acylor-  
ditis and some today a brachy-, it several feet  
square completely filled with <sup>++</sup> them. Got one  
good specimen by taking one. Higher are mostly sea-  
they ditonic slate or sandy dol. that have the  
Olenites and Olenites in a few. Ptycho-  
paria adamsi is a not common form. Saw only one  
brachiopod Rustella edsoni and only one trilobite.

Further out gibb of the same are more dol.  
I do not know what the Parker is here with more  
dols and imbricate dol. than elsewhere. In other words  
it is a series of micaceous slate with lenses and  
zones of dol. Further north there were slate in  
fact from all in a slate.

The question now arises in what is a single  
zone farther north in three fault series, or is it  
simply that the Parker is here in broad undulations  
with distinct zones of dol. In any event that  
I saw today is one in fault relations.

A hot day out in the sun and I perspired  
badly.

Wea.

TUES. JUNE 1, 1909

This zone expresses at least 30' in addition to the main thickness of 1100' at 10° dip.

Wednesday Aug 11 1909

Wea.

FRI. JUNE 4, 1909

Ther.

From a cliff of my name same is about  
150' at thick.

A road was about 500' across, the water  
has a bit of a pool, the road is  
highly by Pender slate.

Then low cliffs of Pender slate where road  
from trail turns short and crosses the telegraph  
short cut line. Dip is about 10 degrees.

Then it is about 1150' to be a bit out-  
crop of a yellowish grey sandstone, about  
1/2 mile thick, about 20' thick.

Then it is about 50' to be a bit of  
stone a road with a water tank and  
with a bit of the same stone, the  
outcrop is about 500' across with the dip about  
9-10 degrees east.

The above gives a bit of the  
series about 430' very much. From 500-520  
and there is a bit of the same stone.

Then there is about 190' of the same  
stone. I will have to figure it out when  
at home.

Have also given up the conclusion in mind  
that all is *Himoraki* as can be seen in the  
road cutting shortly to the north. See next  
page.

Thursday August 18 - 1932

Wea. THUR. JUNE 10, 1909 Ther.

In the north side of the quarry there occurs much of the same material and material here in slate. Evidently the front wall about the Forca Quarry is in the upper part of the group of the enormous, irregularly bedded, and in places, in different beds, of fine grained material. However it may be some of the same material as the many other beds of the same group. The material is moved.

Then walked with a party to my old contact in the north side of the quarry. The contact is in the middle of the group, this is the same as the wall. The material is of the same material as the material in the north side of the quarry. The town men in a marble and no such material as the material in the north side of the quarry. There are some beds of marble in view that it should be Phillipsburg. The material is of the same material as the material in the north side of the quarry. It reached the top of the hill during the night.

Wea.

FRI. JUNE 11, 1909

Ther.

There is here some white crystalline marble  
not more exact, or even in texture as the  
red supposed to be the Phillipsburg marble.  
In any case it cannot be the plane of weath-  
ering, and on the plane one sees no evidence  
of overthrusting or amygdalite.

This prominent one stands about 70' above the  
 level of the land at point, and on approaching  
 it one sees that it is a thin white and other  
 rock contacts. It is a fine dark blue sandy  
 rock apparently composed of metamorphic rock.  
 It is not easy to walk out the bedding and  
 is a fine one. It is also very hard to lick  
 of a different kind than any other of the other  
 rock's here. I have concluded it to be a  
 metamorphosed mass of rolled schist.

This Mallett-Parker contact seen with Howell  
 again on August 23-1909. See for important details.

Beneath the quarry here is the Parker,  
 since it goes west across the mountain road and down  
 it will be the Parker. To the SW is the hill of  
 the

① Parker also appears for miles in the Parker and may

The actual contact not seen. The two masses  
got within 10' of another and here the contact  
is obscured.

Sunday August 21-1932

Wea.

SUN. JUNE 20, 1909

Ther.

Going on north it looks as if there may be one to three  
or more of the banded sandy beds (quartzite) that get  
squeezed and moved through the limestone following around them.  
They are microporous. It appears that some grain may be due to the  
overriding Central Sequence.

The contact level between the Dinoroth and the Phillips-  
burg series is not a horizontal one. It undulates and may  
in some places more than 60' and certainly <sup>can be seen</sup>  $45^{\circ}$  at the first  
broad on the east side of road near the turn on west side  
past the creek, the Dinoroth is down again to the level of  
the road. Farther south it is between 40-50' above the  
road with a good deal of bedding. The top of it may with the  
banded microporous quartzite.

around Tuller, school the level is low and fairly  
flat but directly to E of school there are exposures, Dinoroth  
up to 10' high. A few banded part to the north it is on the  
West side of the road, and in Stevens striking West it makes  
a small fall to the east of the road. There is no quarry  
here evident. There is no fine exposure of the Di-  
noroth. If Phillipsburg is exposed it must be in the  
higher land  $\frac{1}{3}$  to  $\frac{1}{2}$  miles west.

The barner is from St. Albans Hill west to  
 Everett School. For the joint line to day I was  
 able to fix the limits and thickness of the  
 the Hypate slate and the thin St. Albans  
 slate.

This dol. may be in the Hypate slate and is very  
 thin of the Middle Devon. It is of a <sup>very</sup> fine grain and locate  
 it better.

Later on I found the Middle Devon and it looks the  
 position of this dol. Therefore the distance from this Middle  
 Devon to the east bank of Ruff Brook gives the thickness  
 of the St. Albans. Will stop it up to measure.

Monday August 22 - 1934

Wea. THUR. JUNE 24, 1909 Ther.

Dark and very cloudy & did not go out in the P.M.

In the afternoon took the 1:00 P.M. Bus to first road  
 going west after turning under railway. It is 960' N. of  
 main road in the Granting Intl. with one <sup>large lentil</sup> ~~round~~ <sup>of height. in the upper part.</sup>  
 near E-W road, 20' or more across and 10' high. To the E.

A little E. of the first house on south side of road there  
 is a good exposure of a high ortho-oriental dark shale. That of  
 fine to the shaly part. The bedding is hard to see but in 2  
 places I found it to be about 8-10 degrees to E. From here  
 for about 1000' N. of the house is another <sup>and</sup> all is high  
 layered *Oriskany* *Hypocrite* shale. To the W makes a final  
 dip 30' N. E., and has some slate bedding in road  
 one of and the bedding and landing a very clean dip 20'  
 to the S. E. Marked on map.

Further in on line of the slate shore is a local  
 member of *Oriskany* that is 18' x 10' x 10'. Its east of its  
 description full one mile.

The *Hypocrite* may go <sup>W</sup> to see the one house to the N.  
 of road, at least it was with the last. There are two trees.

→ Is the dol. one same last half in the *Hypocrite* or the 24'  
 about 100' N. of house & today there are <sup>some</sup> *Hypocrite* at the  
 road about 300' or more above mentioned house. It was 10'  
 high and had a base of the *Hypocrite* shale. <sup>all of the space of</sup>

Later determined it to be at the base of the *Hypocrite* shale.

This is the true St. Albans slate

Between the two dolomite strata it is 825' apart. At  
 $9^{\circ}$ - $10^{\circ}$  dip 50'. The thickness is  $\approx$  110'.

In Vermont it differs from all other  
thin bedded shales, or thin or coarse bedded  
is St. Albans slate. Formed at the top by the  
West River Co. and below by the Rays Brook Co.

Wea.

SUN. JUNE 27, 1909

Ther.

A fine cool and clear day. Take B. Bus at 9.30  
The dip of the Minorski is 90 to the SE.

There is just in line the transition Minorski and some  
Orwellist. The Minorski goes west to near lake  
and it lies upon the north of the Frick's big vein.

The St. Albans slate here is hard to distinguish  
from the Parker, but is less micaceous than the Parker  
less. The bedding like the Parker is undulating and  
less in the St. Albans. Then too there is less of rusty  
spots. The fossils, however, distinguish both at once.

The St. Albans slate is fine grained, more bedded  
and nearly always so, while the Parker planes are as  
even as a table top. The mica is not conspicuous and  
is usually coarse.

Tuesday August 23-1932

Wea. MON. JUNE 28, 1909 Ther.

Back again to the same road as of yesterday.  
The Ginniselli comes in great exposures marked on the map.

Then it can be strike for about 600' then are no exposures.  
Then appear the massive Mallett in little cliffs that go E.  
to the N.-S. or what I am calling the Puffy Rock road.

Then comes down land in which flows Puffy Rock and in  
which lies the Parker slate part to the Puffy Rock dol. cgl.

The distance to site appears to be around 500' <sup>measured on map</sup> from here

to between the Puffy Rock cgl and the dol. <sup>mi. R. c. g. c.</sup> thought to be  
it is 825' across, and at 100' <sup>on the S in Mill River</sup> ~~is~~ estimated.

Then passed the Mill River cgl from it is <sup>on the S in Mill River</sup> ~~is~~ <sup>on the S in Mill River</sup> ~~is~~  
north to the N.-W. road which became this morning. This led  
to a surprise that a dol. zone is not to be taken as distance  
but along another with. From the cgl. to the dol. zone it is  
510' across to the top of the dol. zone. The dip of the dol. zone is  
15° N.-E. Then from the dol. zone to the cgl. zone it is 1335'  
across at an angle of 10° or more (bet 7° and 10°).

Tomells pits of cgl when he collected U.S. fossils  
is as the very top of the formation. It is a few Cyprina  
and Almygdalin in the cgl.

The Mill River cgl strike the front slate, comes and  
goes. Here it is not over 8' thick and further N. there is

This zone looks much like the transition zone between the Orinoco - Mallet dol. seen in the Burney Quarry S.E. of Oran.

With this dol. there are 3 others in the Páucar making from all in the Páucar state.

This presented one of us? the dol. to the weathering zone.

This Mallet maybe the weathering zone, and not as it are it on the map. where there much the low.

Thursday August 25-1932.

Wea. SAT JULY 10, 1909 Ther.

It remains a hot day and as I am tired from yesterday, remained out of the hotel during the morning.

At a hot day but at 12.30 P.M. I am off in the Buick for the road pay E. by Rockledge. E. of the Breenton road about 60' above <sup>the water level</sup> one sees an amphibolite-like outcrop <sup>in the E-W. road</sup> with much interbedded slaty sandy Parker-like <sup>slaty shale</sup> state. There is higher coarse Parker slate some of which is badly crumpled. Evidently this is another member <sup>of the</sup> sequence to be in some of the other Mattett and all of the Parker slate.

To the north of the second house <sup>at</sup> <sup>the</sup> <sup>road</sup> <sup>is</sup> <sup>a</sup> <sup>small</sup> <sup>quarried</sup> <sup>cliff</sup> <sup>of</sup> <sup>Parker</sup> <sup>slate</sup> <sup>dis</sup> <sup>of</sup> <sup>10'</sup> <sup>to</sup> <sup>20'</sup> <sup>thick</sup>. E. <sup>of</sup> <sup>this</sup> <sup>is</sup> <sup>another</sup> <sup>dol.</sup> <sup>one</sup> <sup>10'-20'</sup> <sup>thick</sup>. <sup>Point</sup> <sup>is</sup> <sup>the</sup> <sup>Mattett</sup> <sup>dol.</sup> <sup>is</sup> <sup>at</sup> <sup>the</sup> <sup>base</sup>. This dol. and the older Parker slate shows the same <sup>crumpled</sup> <sup>fractured</sup> <sup>and</sup> <sup>chopped</sup> <sup>blocks</sup> <sup>of</sup> <sup>various</sup> <sup>sizes</sup> <sup>into</sup> <sup>the</sup> <sup>slate</sup>. <sup>There</sup> <sup>is</sup> <sup>one</sup> <sup>example</sup> <sup>of</sup> <sup>the</sup> <sup>bed</sup> <sup>of</sup> <sup>the</sup> <sup>same</sup> <sup>kind</sup> <sup>as</sup> <sup>seen</sup> <sup>at</sup> <sup>the</sup> <sup>base</sup>. <sup>There</sup> <sup>is</sup> <sup>one</sup> <sup>more</sup> <sup>marked</sup> <sup>Mattett</sup> <sup>dol.</sup> <sup>at</sup> <sup>the</sup> <sup>base</sup>. <sup>Followed</sup> <sup>E.</sup> <sup>by</sup> <sup>one</sup> <sup>of</sup> <sup>the</sup> <sup>older</sup> <sup>and</sup> <sup>a</sup> <sup>then</sup> <sup>another</sup> <sup>dol.</sup> <sup>then</sup> <sup>a</sup> <sup>long</sup> <sup>stretch</sup> <sup>of</sup> <sup>Parker</sup> <sup>slate</sup>.

In the vicinity of the <sup>road</sup> <sup>at</sup> <sup>the</sup> <sup>base</sup> <sup>of</sup> <sup>the</sup> <sup>road</sup> <sup>is</sup> <sup>the</sup> <sup>Breenton</sup> <sup>conglomerate</sup>, here about 300' from the Highgate road. Here may be what appears to be the contact between the Highgate slate and the Breenton cal.

The ls. pieces in the cgl. appear to be of the lentils  
and in the sand granitic in nature. Then headed Milton.

This piece is in the shape of words found in the  
E. by the same wall. It is sometimes hard to locate.  
Directly over is a sand piece. The St. Albans is  
superior to the ls. - the W.

Sept. 5-1932 { 37' according to Logwood  
= 5'-80' thickness }

Evidently the King's (18th) eye is made up of the light  
dls. in the Pecten, broken up and recombined by sand  
ground sand and dolomite parts. When seen is not dol.  
shale some of the ls. of the same of all. Such com-  
plexes are impossible to locate.

Thursday August 25 - 1932

Wea. Mon. JULY 12, 1909 Ther.

The Georgia slate <sup>above the highest slate</sup> <sup>is</sup> <sup>represented</sup> in grey slate  
without its pieces. About 5' higher a  
few pieces of the Lenoir ls are introduced, and 10' above  
base they are more common and the pieces larger upto  
10" <sup>across</sup> in a 10' zone by one mile common,  
and then decreasing in the irregular Devonian ls. <sup>ls. con.</sup>  
Some thin beds of Lenoir ls are <sup>ls. con.</sup> <sup>seen</sup> <sup>at</sup> <sup>the</sup> <sup>base</sup> <sup>of</sup> <sup>the</sup> <sup>zone</sup>. There  
is more thickness of ool towards the road about 300' to

It is 21 miles north of St Albans to  
these good loc. found by Ulrich in the typical  
Milton.

See previous notes on visit of July 17-  
1932 in this note book.

Loc. name Highgate slate in place.

Monday (August) 29-1932

Wea. THUR. JULY 22, 1909 Ther.

A dark and threatening morning but con-  
sidering it to go south of Milton to study field  
area of the Milton district. Took the 9:30 A.M.  
bus to Burlington. Got off 40 miles south west of  
Milton and looked again at the hills, looking S.  
Saw the crinoid stems and other things in many of the thin beds etc. All are massive due to  
sulfur <sup>rich</sup> etc. that are more or less vertical and intra-  
formationally conglomeratic. The sand or siltstone, fine but  
in places, conglomeratic and the clay is hardly a  
quartzite. Its dip is many to be E at  $15^{\circ}$ - $20^{\circ}$  and  
then may be NW or more of the dip towards the S.W.

Further south I looked at more of it. but saw no  
fossils. On some of the bedding surfaces, the sand  
nature of the bed is seen. Usually the beds are  
small less than one inch long, but may be one  
foot up to several inches across. On other places  
I saw large blocks, some many feet across. These  
appear to be intraformational. The masses that  
I saw are more like of the bottoms and can be seen  
about and over the deposition surface of them.

About one P.M. got to White, loc. 2, July

There is no regularity esp. here with pieces  
being Heldeby fossils. It must be a case of  
very identification. Here the chert, weather  
out much chert and irregular chert, some of  
it blackish chert, and large lumps of sand to which  
more quartz has been added during weathering. The  
whole surface is extremely jagged and studded  
with chert and quartz lumps. No fossils.

On higher layers with con. chert there  
are det. that weather out lots of siliceous  
Clavellias and rarely trilobites. Not a  
number of good specimens and I hope some  
of the red will show out more specimens. The  
trilobites clavellias are very small and very  
poor. Some of our fossiliferous which I have  
later along.

In all of the det. seen today, there is nothing  
to suggest the thin bedded ls of the Highgate  
zone that I used to call Minisquiri. It is not  
advisable to call the latter Milton since it  
is totally dissimilar lithologically and fauna-wise.  
Both are known Upper Cambrian.

Wea.

SUN. JULY 25, 1909

Ther.

If there is no northward penetration should be high-  
 grade banded slates to the N. of the main highway.  
 If there is Colorado - where the dip has again  
 reversed from what it is at Wichita Ave. 3.

I hear the house at the apex of the road but on the  
 S. going from the road down a steep dip. contains lot  
 of dried petroleum. As the original rocks are high  
 grade slates this oil must have come from there  
 and leaked down into the dip. I have two samples.

Ther.

not appear to be any other <sup>near</sup> 200' thick, the distance from  
the quarry to the Milton may be 200' or at most 300' across.

The hill with the quarry and the Milton is very narrow  
and then a very wide shallow basin in the gorge seen  
yesterday - say 80'. Maximum on map.

Then walked <sup>one mile</sup> N. on the St. Albans road to the first  
E. facing road. Then the Milton is no wider <sup>at this point than south</sup> but I marked  
Milton in my map further east with blue ls. just as can  
only occur with ~~some~~ <sup>massive</sup> ls.

The next place I was on my map <sup>at this point</sup> is a little  
a little south of the banded lower St. Albans, and  
of ls and thin shaly <sup>ls</sup> <sup>one inch</sup> <sup>massive</sup> <sup>ls</sup> <sup>massive</sup>  
interbedded with a few thin shaly ls. some occasional  
interbedded ls <sup>one</sup> <sup>up to</sup> <sup>a</sup> <sup>foot</sup> <sup>thick</sup>. Too light  
to look for fossils and <sup>also</sup> <sup>in</sup> <sup>the</sup> <sup>part</sup>. The <sup>color</sup>  
test is decidedly <sup>blue</sup> and makes it next to <sup>impossible</sup> to  
get them.

About one-half mile <sup>west</sup> <sup>of</sup> <sup>the</sup> <sup>last</sup> <sup>place</sup> <sup>is</sup> <sup>the</sup>  
large fisherman with <sup>the</sup> <sup>St. Albans</sup> <sup>slate</sup>. It is <sup>noted</sup> <sup>on</sup> <sup>map</sup>.

On the south facing road at the place marked <sup>St. Albans</sup>  
Milton here is the <sup>usual</sup> <sup>type</sup> <sup>of</sup> <sup>interbedded</sup> <sup>ls</sup> <sup>and</sup> <sup>slate</sup>  
and <sup>thin</sup> <sup>bedded</sup> <sup>ls.</sup> <sup>in</sup> <sup>the</sup> <sup>upper</sup> <sup>part</sup> <sup>of</sup> <sup>map</sup>. This <sup>is</sup>

all appear to be above the lower black slates with  
interbedded quartzites and the fossiliferous dolomites.

Curiously one sees very little of it in place, the one  
road met at any one place. But there is  
much eroded ground.

Friday September 2 1902

Wea.

MON. AUG. 9, 1909

Ther.

A fine bright but overcast morning, but down off 5 to make the traverse N. about 1 1/2 miles S. of Highgate.

All is Champlain sand and clay to near Highgate Brook where the level has risen some over the level of Highgate. To the north and south and N. down the brook there are fine displays of the many vertical beds of the Highgate slate. A little south is the roadcut quarry in the thin bedded ls of the Lower Highgate. More south is a massive dol. sandstone seen at the top of the Missisquoi. Then in front of the massive sandstone is a shaly further south is the thin ls of the Mill River. It extends south of the road and forms just mentioned and on both sides of the road. In the distance of a quarter mile one passes through the trees of the birch, willow and probably none of it is in the Highgate beds.

The dip of the Mill River is very low, less than 10° N.E. Of Highgate Brook <sup>about</sup> 200 yds, the east, small piece of the limestones and the shaly <sup>is</sup> seen. In general it seems to be tilted upward from the east, but approaching it from the N. one sees from its bottom that it is bounded up with the lower Highgate and the top of the Missisquoi. Still further south to W. <sup>Highgate</sup> <sup>road</sup> there is much massive dol. and to the N. of it is a wide area of Highgate slate. This

Wea.

This dol appears to be the  
base of the Missisquoi  
formation. See if you can.

Wea. THUR. AUG. 12, 1909 Ther.

This cannot be the Inverton Congl. since it appears  
one mile east at the Highgate road.

These great dol. blocks are pieces in the cgl. and  
more broken than one of the Park dol. zones.

This connection is not correct. Redrawn in terms  
of notes and maps.

Friday Sep. 2 - 1932

Wea. FRI. AUG. 13, 1909 Ther.

Full River on the Swanton conglomerate. Towards the north it appears to be made like the Mill River in having many thin pieces of the L.C. lentils. It also has much sandy dol. and got shingles of the Parker slate. Farther west than in the Acadia formation it is a dolomite congl. with the blue under 1/2' or 1' in, but there occur also thin masses each 15 x 10 x 10 of a very sandy dol. All these dol. beds weather a rusty red. Near the Mill River a <sup>reddish</sup> thin is a large flint chert <sup>lenticles</sup> scattered all along up by the weather but originally it must have been an <sup>1</sup>/<sub>2</sub>' thick bed and 50' wide. According to Leassee that the L.C. surface was mostly of the same nature pieces of <sup>1</sup>/<sub>2</sub>' and <sup>1</sup>/<sub>4</sub>' and <sup>1</sup>/<sub>8</sub>' and <sup>1</sup>/<sub>16</sub>' of dol. noted last week on the Swanton road in the darker. These are the <sup>same</sup> <sup>as</sup> seen <sup>in</sup> the <sup>red</sup> <sup>at</sup> <sup>the</sup> <sup>base</sup> <sup>of</sup> <sup>the</sup> <sup>congl.</sup> All the chert is <sup>at</sup> <sup>a</sup> <sup>depth</sup> <sup>of</sup> <sup>about</sup> <sup>10</sup> <sup>'</sup>.

Leassee the topography seen near the <sup>water</sup> bridge here, other with a little earlier in the <sup>later</sup> <sup>of</sup> <sup>the</sup> <sup>Mississippi</sup> and another north older and older <sup>than</sup> <sup>the</sup> <sup>one</sup> <sup>seen</sup> <sup>in</sup> <sup>the</sup> <sup>east</sup> <sup>of</sup> <sup>the</sup> <sup>conglomerate</sup> <sup>dol.</sup>

Marked this place on the maps.  
The thickness of this zone is at least 30'

Collected more boundary markings, and so now I  
have a large box of roots. Their hollow lies in the  
middle of the specimen out of the hand ls.

Saturday Sep. 3 - 1932

Wea. TUES. AUG. 17, 1909 Ther.

A bright cool morning, and I am off to get down Humphreys Brook.

All is Highgate slate down to the falls where the more dense beds make the falls and <sup>appear to</sup> dip down stream or N.W. about  $20^{\circ}$ - $25^{\circ}$

Farther down stream <sup>but on top of the former</sup> <sup>strata of</sup> some of them are massive dolomite <sup>some of it</sup> <sup>is</sup> <sup>in</sup> <sup>the</sup> <sup>form</sup> <sup>of</sup> <sup>interstratified</sup>.

Then the little valley widens in places and we see no up-  
folds along the stream. I walk down the brook far  
enough to see that our cross stream hills are <sup>not</sup> <sup>any</sup> <sup>long</sup> <sup>at</sup> <sup>all</sup> <sup>in</sup> <sup>the</sup> <sup>direction</sup> <sup>of</sup> <sup>the</sup> <sup>stream</sup>.  
They are <sup>not</sup> <sup>any</sup> <sup>long</sup> <sup>at</sup> <sup>all</sup> <sup>in</sup> <sup>the</sup> <sup>direction</sup> <sup>of</sup> <sup>the</sup> <sup>stream</sup>. They must  
be beyond when I was.

Returned to the <sup>camp</sup> <sup>at</sup> <sup>the</sup> <sup>end</sup> <sup>of</sup> <sup>the</sup> <sup>day</sup>.

Learned nothing new this morning.

In the afternoon tried my luck on the Highgate  
gorge to see if I could get some fossils in the <sup>upper</sup> <sup>part</sup> <sup>of</sup> <sup>the</sup> <sup>gorge</sup>  
and finally <sup>collected</sup> <sup>a</sup> <sup>few</sup> <sup>specimens</sup> <sup>of</sup> <sup>the</sup> <sup>same</sup> <sup>kind</sup> <sup>that</sup>  
yielded a mass of <sup>specimens</sup> <sup>of</sup> <sup>the</sup> <sup>same</sup> <sup>kind</sup> <sup>that</sup>  
and <sup>found</sup> <sup>nothing</sup> <sup>new</sup> <sup>in</sup> <sup>the</sup> <sup>course</sup> <sup>of</sup> <sup>the</sup> <sup>day</sup>.  
Returned to work this afternoon.

Wea.

WED. AUG. 18, 1909

Ther.

Next day, had Logwell calculate the thickness and he made it 55' plus the 8' or so of the basal conglomerate.

Sunday. Sep 4-1932

Wea. THUR. AUG. 19, 1909 Ther.

Windy warm morning with rain in the air. Showered twice during the day.

Spent 2 1/2 hours in the gorge at Highgate Falls and it is a lot more of the hillside on the gorge.

Then packed up ready to leave for Granton this afternoon. Packed a large basket with tools.

Left Highgate in Mrs Smith's car at 3:45 for Granton where the S.P.M. Bus for St. Albans will pick me up.

Put up for the night at The Tavern and will go to the station on the morning train.

Looked over all the lower part of the Minningford and concluded they must be 80'-100' thick. I tried to get a cross section and make it 75 feet wide a dip between 15°-20° calculated thickness at the base. At 20° it is 75. This is correct.

Shortly after 7:30 the Tavern who should turn up but I spoke with Mr. and Mrs. of Boston. It is arranged that I will see them on Monday and show them some of my specimens. This I agreed to do.

Wea.

FRI. AUG. 20, 1909

Ther.

This place Keith now correlates with the  
 Millerian cgl. or at least with the cgl. in the  
 gorge. It is a little easier than this to do, since  
 the Millerian is a basal cgl. which none in  
 the gorge is not. The cgl. No. of Shells Common  
 is that a basal cgl. at Swanton.

By traverse east and along  $\Gamma$  dip  $20^\circ$   
 the thickness is  $70'$

Monday Sep. 5-1932

Wea. MON. AUG. 23, 1909 Ther.

The 26' egl. in the Strigata zone Longwell does not appear as the same as the Mill River egl. It is certainly not a basal egl, but a egl in an unconformable sequence, and it appears to Longwell to be rather an interformational one. In any event it is very at present to call it (Miller's).

He should have a name for the Missisquoi beds. Also for the lower dolomite because they would be formally directly correlated with the Westport dolomite, <sup>Phillips</sup> ~~Phillips~~.

The egl at the base of the St. Albans west of Rockledge Cove, well named but will Ruff have but he would in any event named the egl, and the associated dol. as marking the base of the St. Albans. The calculation of the total thickness of the St. Albans here as about 70' thick.

At the "P. Energie" loc. Longwell regards it as a part of the Phillipsburg series, but he notes it is interbedded with the marble strata. He says the Phillipsburg is here in fossils (diag. fossils), is a local fossil.

Wea. WED. AUG. 25, 1909 Ther.

State him state it from my paper. Later  
today we crossed and the same strata on the  
S.E. side of the Florida canyon. It is an incom-  
plete but decided columnar structure well  
and is well water exposed. All the strata have  
dips in the same direction and rather steep ang-  
les from 200- north 400. See the circular well  
that may well find the water to be, also  
having a good, dry, aged, state. Can these beds  
be crazy?

In the Florida quarry I myself at first was  
not inclined to accept my view of the strata  
being mentioned in the Phillipsburg series, but  
thought it due to normal faulting. I also in face  
of my view and held it to be the primary con-  
struction on the eastern side, but that there  
also normal faulting in connection with it. Got  
him to state the structure from my paper.

Raywell etc went in to Cambridge at 5 P.M.

I took a train home the next day and  
got to New Haven before 6 P.M.

WED. SEPT. 1, 1909

Ther.

Got to the Dist. Soc. House on Dr. 117 street at 7:50 A.M. The bus did not turn up until 8:30 and Bird and I were loaded and off to the north. The day went well and I was caught in a small town at the Union quarry.

Tuesday July 11-1933

James turned up and the other, or that was one of the - put 30.

Saw the Pitohui from Harry across of Cyprian's room. South Hall is now operating a small office to what it is now. Evidently he wants to sell in the course of time, but just now he is developing the Cyprian room for the present.

Left Lake City at 6:45 P.M.

Wednesday July 12 1933.

Wea. THUR. SEPT. 2, 1909 Ther.

Had a fine clear day in the Adirondacks. Seeing Archeologic rocks  
Granville Linn. Mrs. Lady attend and  
Annapolis.

In the afternoon Gilleuly got lost  
and we did some much work.

Thursday July 13 - 1933.

A cool night and a perfect morning  
in the Adirondacks.

Today saw of the same Archeologic  
rocks and finally the Potsdam sandstone  
of the same chain.

Continued with the International Geologists to Hartford. Then returned to New Haven. The evening of the 19th.

On the evening of the 20th we all visited the Peabody Museum.

On the 21. Lippell had met to lunch to tell me about the details of the trip.

Wea.

MON. SEPT. 6, 1909

Ther.

Saturday Aug. 26-1933

Left at midnight in sleeper on  
 Montreal train for St. Albans, Vt.

This trip is to see what B.F.  
 Howell has got and out of harmony  
 with my results.

St Albans, Vt.

Sunday August 27-1933

Arrived 30 minutes late, to some  
 amount overdue at New Haven.  
 at St. Albans

Put up again at the Warren.

At 11 A.M. team of mules or horses  
 to the Barney marble Quarry near  
 Swanton. Object to find the cutting  
circulate layer. Hunted fruitlessly  
 for it and failed to find it. Saw some  
 sillite in lower part of Parker that  
 looked like the rock having these joints  
 and so it may be the same from the  
 Parker; if not they are only the shale.

Wea.

TUES. SEPT. 7, 1909

Ther.

Got on it and turned out to be Highgate  
with zones of dolomite and hard sandy slate  
thin weathered out by a ridge marker.

On Tuesday when I was here again and above  
I could find none of the same fossils. Out of the  
same shale has large *Agnostus* but from  
*Agnostus*.

Monday, Aug. 28 - 1933

Wea.

WED. SEPT. 8, 1909

Ther.

St. Albans, Vt.

At 8.30 A.M., Dr. Howell calls for me and in his car goes off to the north via the highway road.

First we went west on the County road to the H. W. Alden farm. In general it would <sup>be as good as</sup> ~~be~~ the ~~same~~ ~~as~~ ~~the~~ ~~one~~ ~~we~~ ~~found~~ ~~before~~ ~~and~~ ~~the~~ ~~stratigraphy~~ ~~with~~ ~~the~~ ~~large~~ ~~fish~~ ~~bones~~. Beyond is the rock ~~mass~~ ~~is~~ ~~not~~ ~~quite~~ ~~so~~ ~~high~~ ~~as~~ ~~the~~ ~~one~~ ~~at~~ ~~the~~ ~~park~~. He thinks it is a deposit of ~~the~~ ~~same~~ ~~age~~ ~~and~~ ~~not~~ ~~a~~ ~~fresh~~ ~~one~~ because we see no evidence of ~~fresh~~ ~~ing~~ ~~or~~ ~~of~~ ~~any~~ ~~of~~ ~~the~~ ~~same~~ ~~age~~ ~~as~~ ~~the~~ ~~one~~ ~~at~~ ~~the~~ ~~park~~. <sup>land</sup> ~~is~~ ~~not~~ ~~a~~ ~~deposit~~ ~~of~~ ~~the~~ ~~same~~ ~~age~~ ~~as~~ ~~the~~ ~~one~~ ~~at~~ ~~the~~ ~~park~~.

Under the ~~stratigraphy~~ ~~of~~ ~~the~~ ~~park~~ beneath the great double Elm he got the same ~~kind~~ ~~of~~ ~~material~~ ~~which~~ ~~is~~ ~~a~~ ~~guide~~ ~~to~~ ~~the~~ ~~same~~ ~~stratigraphy~~ ~~etc.~~ ~~It~~ ~~is~~ ~~not~~ ~~clear~~ ~~to~~ ~~me~~ ~~how~~ ~~to~~ ~~use~~ ~~the~~ ~~stratigraphy~~ ~~to~~ ~~find~~ ~~out~~ ~~the~~ ~~stratigraphy~~.

One then mentions the ~~quarry~~ ~~road~~ ~~metal~~ ~~quarry~~ ~~one~~ ~~mile~~ ~~N.W.~~ ~~of~~ ~~the~~ ~~park~~ ~~and~~ ~~the~~ ~~quarry~~. Considerable ~~material~~ ~~has~~ ~~been~~ ~~found~~ ~~since~~ ~~last~~ ~~year~~. I explained to Howell where to get the stratigraphy.

Wea.

THUR. SEPT. 9, 1909

Ther.

Later work. did that this congl. is due to sea floor sliding. The beds are too irregularly deformed above and somewhat below it to be a deposit of this age.

1

These fossils turned out to be uppermost Parker, but several *Clencidos*.

Monday August 28 - 1933

Wea. FRI. SEPT. 10, 1909 Ther.

arsenite and berthelid, and below the empl.  
the chert, roema ochrolepti. The dol. con-  
glomerate is of a depositional one across  
an erosion surface. The igneite must follow the  
unconformity is an igneite concretion but not the  
Parker but more like Cambridge. He does  
not believe the "Mallett" to be part of Lower  
Cambrian but is more like Cambridge. This  
because the igneite is to be part a few  
feet thick, but he is not sure about the  
place, but evidently igneite concretion are  
Cambridge.

The igneite is to see dol. concretion back  
of the chert concretion encircled on map just to  
the south of line A in the diagram concretion  
name. Keith and I saw and then it is concretion  
It is a small concretion just to W of the "Mallett"  
a depositional concretion. The igneite concretion concretion.  
Took also a concretion concretion concretion concretion  
concretion. I should revisit in concretion concretion concretion  
concretion detail.

Wea. SUN. SEPT. 12, 1909 Ther.

One been turned around and cut off south  
about 3/4 miles to the place where Howell found  
possibly? part eye. It is directly south of a house  
located on my field note. It is on the western  
side of Mt. Keith and has been called Mal-  
lett. Going up to find to be with the farmhouse  
we were in and found the quartz to be west  
toward the Grinnell - Mallett and in the  
middle of last part of the Parker. How we see  
the following sketch looks like the above in the  
formation.

Then entered S.V. to Grinnell and  
lunch at the Park Hotel.

Took us west to the creek, roughly one mile (h.  
of direction function. First we went west to the mountain  
to see the best exposed contact between the Mallett  
and older. I saw it first seen on Aug. 19-1932 but  
made little if it other than the contact (see above page).

The Mallett is eroded with undulations as  
much as 10' high. To north the unconformity is greater  
and the Parker shale goes down the hill. Then

Wea. MON. SEPT. 13, 1909 Ther.

Monday, August 28 - 1932

Wea. TUES. SEPT. 14, 1909 Ther.

can't see no drift but there is here a hard bottom  
the Hallett and Parker, sand and gravel. This  
explains why so often the Lower Parker has  
much dolomite pebble inclusions that weather  
out leaving holes. Thirteen yards across the  
Parker above the Hallett contact is  
same dol in sh.

Then turned east on Leavenworth St. west  
to New Republic. First examined the Kellogg  
Alonides quarry. It is claimed to be un-  
mistakable Parker shale below, higher the dolomite  
sh has just beneath the sh, no dol. has to Alonides.  
Further east Howell would admit no distinction  
in the Hallett the rounded sh. and higher dol.  
to Kellogg (740') dol. Further east is  
nothing but a red shale. Examined but to this  
I would not agree. Then turned up a high ridge  
plateau in dol. sh on the eastern slope of the  
hill. Howell was then convinced that all is Par-  
ker with here a red bottom.

It is very probable that these Parker dol. are  
all in lenses dipping toward the east by N-S.

Wea.

WED. SEPT. 15, 1909

Ther.

This dol. and congl. makes a low anticline,  
below this congl. and dol. lies the highest Parker.  
In fact these dol. congl. look like Ross Brook, not  
however in the Middle C. or up.

Monday August 28-1933

Ther. Wea. THUR. SEPT. 16, 1909 Ther.

More dol. lenses occur farther E to N. of road. These I studied last year and the sequence E. is described with a list of Aug 19-1932

In the lowest Parker dol. there are local congl. with dol. inclusions up to 100 ft. long. These are intraformational. Originally Howell was made up these Mill River and so came to the idea that all higher in the sequence is of Mill R. age. He found it all up.

My anticline in Parker is then east or to some road and described last year continues more Parker part for 400 yards to the congl. see the description.

At the eastern end of same road the Parker is overlain by a very sandy dol. at one point is dol. conglom. with thin slaty dol. pieces and pieces of limestone that may be intraformational or out of the L.R. This might be base of the L.R. Then E. for 150 feet is a sandy dol. from 3'-5' thick and runs out in places to it up to 10 miles away. In places the dol. congl. occur the best horn-like fossils. Further east about 50' is another shale ridge and it also has the horn-like fossils. The congl. is over out of it. Between the two congl. is a local lense

Wea. SUN. SEPT. 26, 1909 Ther.

Stets head surface and in the road meter gauge  
and dip and should be a good place to set fossils. I  
inspected the small creek and he said he would  
return to make a collection.

At this place the dip is maintained by a  
small thin layer of *Trilobites* which is not  
any of regular *Trilobites* but is *Trilobites*.

Then entered the <sup>side</sup> of the 1/2 mile and a cut in  
the road to the West. *Trilobites* *Trilobites* *Trilobites*  
cliff of high state *Trilobites* *Trilobites* and with  
which together lie *Trilobites* *Trilobites* *Trilobites*  
5' to 6" of *Trilobites* *Trilobites*. I see *Trilobites* *Trilobites*  
got some *Trilobites* *Trilobites*; it is a *Trilobites*  
ls and not the same as *Trilobites* ls. The  
place is *Trilobites* *Trilobites* *Trilobites* *Trilobites*  
to west of the road, and *Trilobites* *Trilobites* *Trilobites*  
at the west of the road which is *Trilobites* *Trilobites*  
the *Trilobites*. To west *Trilobites* *Trilobites* *Trilobites*.

Next entered the *Trilobites* *Trilobites* *Trilobites* and then W.  
(and *Trilobites* to spot the *Trilobites* *Trilobites*) to see contact  
between *Trilobites* and *Trilobites*. Here the latter

Wea. MON. SEPT. 27, 1909 Ther.

This place is roughly located. It is on the St. Albans  
quadrangle N.W. of Georgia Center about four miles.  
It is just north of Little D in Georgia Township and  
shortly to W of Mill River. It is spotted on maps.

Tues Dec August 29 - 1933

Wea. TUES. SEPT. 28, 1909 Ther.

for about 6' is decidedly conglomeratic with angular pieces of a white qtz. The pieces are usually small under 6" but saw a piece 18" across. This Mailet is near the contact though not at the actual contact which is not exposed. Have a sample of it. The contact is about as follows:

W. Prinosaki, dip E. 80-100

~~Engl. Mailet, base fine  
 thin engl.  
 Crinoidal base int. 2-10 y 1900~~

In places the basal layer of Mailet is a qtz. followed by the engl. bed, which is intrapromontal. These engl. Mailet beds occur also at higher levels as well as seen further on in these notes. It would be wrong to impress one that there is a sharp break between the Prinosaki and Mailet. Look into this matter, and maybe I had best for you to write out for me if other places showing the details of the contact.

Look up in Mailet engl. localities N.W. of St Albans spotted on my map.

As we entered N.W. Georgia Main House printed <sup>out</sup> that he likes to W. if he read as all do.

in case there be Parker Little dit. Shows out  
to nothing. I am to be getting to O'Connors place.  
Here the dit. appears and may be 100' thick  
and then out to very little before getting to W. of  
H. Adams. But here the dit. is contained by  
the Middle Cambrian and underlain by  
the lower slate.

At my "Mid. C." locality of last year if  
we interpret my "Buff. Brown" dit. as the same  
as Parker's Little dit. then the dit. appears to thicken  
~~out~~ to S. West of Connors house of the  
P. & N. is 100' and in Connors we might say  
that from Parker's Little much has been  
eroded off. All this could be worked out by  
tracing out the dit. Maybe Howell has  
the dit.

Tuesday August 29 - 1933

Wea. THUR. SEPT. 30, 1909 Ther.

and of the same age as the dol. at Parker  
 Cattle. The thickness here <sup>by the dip</sup> <sup>and by the dip</sup> <sup>and by the dip</sup>  
 would <sup>appear to</sup> be <sup>thick</sup> <sup>than</sup> <sup>any</sup> <sup>other</sup> <sup>dol.</sup>  
 N. Howell is supposed to have it in the N.  
 C. <sup>and</sup> <sup>that</sup> <sup>it</sup> <sup>may</sup> <sup>be</sup> <sup>one</sup> <sup>of</sup> <sup>the</sup> <sup>Mil-</sup>  
<sup>ton</sup> <sup>dol.</sup> <sup>that</sup> <sup>thickens</sup> <sup>S.</sup> <sup>to</sup> <sup>the</sup> <sup>100</sup> <sup>feet</sup>  
 seen <sup>with</sup> <sup>little</sup> <sup>hill.</sup> I am disposed to refer  
 it to the Lower Cambrian, but <sup>with</sup> <sup>some</sup> <sup>uncertainty</sup>  
 found <sup>in</sup> <sup>the</sup> <sup>same</sup> <sup>area</sup> <sup>as</sup> <sup>the</sup> <sup>upper</sup> <sup>part</sup> <sup>of</sup> <sup>the</sup> <sup>same</sup> <sup>series.</sup>  
 The whole said, however, that the Parker is <sup>marked</sup>  
 by a marked division into <sup>two</sup> <sup>parts</sup> <sup>which</sup> <sup>are</sup> <sup>very</sup> <sup>variable</sup> <sup>in</sup> <sup>thickness</sup> <sup>and</sup> <sup>color.</sup>

more probably a <sup>single</sup> <sup>series</sup> <sup>of</sup> <sup>beds</sup> <sup>of</sup> <sup>limestone</sup>  
 time and covered by sea <sup>the</sup> <sup>is</sup> <sup>filled</sup> <sup>with</sup> <sup>water</sup>  
 these <sup>are</sup> <sup>the</sup> <sup>same</sup> <sup>as</sup> <sup>the</sup> <sup>ones</sup> <sup>found</sup> <sup>by</sup> <sup>the</sup> <sup>100</sup> <sup>feet</sup> <sup>dol.</sup>  
 Thus

<sup>water!</sup>  
 That is, the 100 ft. as Howell writes, I saw it Sep. 4  
 and saw <sup>it</sup> <sup>was</sup> <sup>the</sup> <sup>same</sup> <sup>as</sup> <sup>the</sup> <sup>one</sup> <sup>at</sup> <sup>Boyer</sup> <sup>locality</sup>  
 may be 40'-60' thick.

Wea.

FRI. OCT. 1, 1909

Wea.

SAT. OCT. 2, 1909

Ther.

Am. came to surprising thing, the dip. My  
new place of last year for "Mid. Camb. con. tubes"  
not to be wrong. There is no M.E. here and the  
highgate directly makes a decidedly con. d. d.  
that I called the "Ruff Brook" but which must  
be the Parker d. d. seem to be S. some  
thicker. The fact, as we follow.

My "Ruff Brook" d. d. con. is <sup>at</sup> high-  
gate dipping E. at a low angle. If this angle is pro-  
jected W. to the N.-S. road it is seen to receive  
Parker state considerably distorted and folded.  
It makes the surface of the hill rising to the  
W., and may be no thicker than the main out-  
ing Parker little 30' thick.

On my "Ruff Brook d. d." now a covered  
area and to the E. is the little hill, a bedded  
state having the trilobites. Now I know the top of  
St. Albans age and which probably are a common  
highgate time. In the quarry, however, I  
found the brown <sup>con. d. d.</sup> <sup>con. d. d.</sup> and it also occurs  
in the quarry where I got the trilobites. All the  
one found here and a trilobite head. However  
place for fossils is on north side and here he  
got few specimens, but some fossils and one

about 335 yards, and hence in 350 down the dip slope to the Rapp Brook engl. the beds dip about 80-90. As the hill from the Caryl. is about 80 feet high, this height should be subtracted from the thickness indicated by the 300 yards distance. Howell feels the total thickness of the dolomite does not exceed 100'. At one mile N. on the St. Albans E-W road the thickness is not over 30'.

Had dinner with the Howells (father, mother and son, about 17 years old) at their farm, may have at shore of St. Albans Point facing Lake Champlain. Howell delirious and me as the Tavern a little after noon's sleep. I retired at once, tired out.

Really to St. Albans may start in shortly  
to New Champlain County Club House.  
The pit outcrop of Parker starts in at  
about 249 on map.

Wednesday August 30-1933

Wea.

TUES. OCT. 12, 1909

Ther.

Wrote up during the morning my notes of yesterday.

On the late afternoon walked N. on the Invention road to see the Mill Run outcrop  $2\frac{1}{2}$  miles N. of St. Albans. The Mill Run at the base of the Highgate is the regulation one made of <sup>only</sup> fisherite <sup>pieces</sup> found by a sand-dol. At the N. end of the little outcrop is a diagonal at least to some extent. The entire outcrop is 18 yards across, but the dip cannot be made out and the structure is strong to some extent.

It is uncertain to state that must be to St. Albans. The entire outcrop is 18 yards across. It goes N. on Invention road <sup>diagonal</sup> to about 200 yds. on map as indicated where the Park appears and goes on a little for a long distance. It is indicated on map.

The Mill Run pit appears again among the trees in the top of the gravel containing a little to N.E. of the one in the vicinity of the site.

The apparent dip about  $30^\circ E$  of the Mill Run is probably the foresetting. The actual bedding cannot be made out.

Then turned S. and trace west along county road to R. R. crossing (H. Central). Then S. on R. R. just bench mark 291, across county road near 295 on map, and about  $\frac{1}{4}$  mile farther S there is a railroad cut through the Parker. A small arch in strata here. At many levels the Parker is replete with intraformational dol. pieces all sharply angular, usually small but some are one foot across and one block was seen about 2 feet across. To E. of railroad in Cow Justice more Parker is seen with the same congl. Here was remnant of dol. lense 6' thick and still 10' long. Fracture have been broken some 4' in diam. Farther E. is more dol. lentils. Evidently here dol. lentils are farther from the mass and now the broken up by the sea and redeposited as intraformational congl.

Farther S. on R. R. the Dinorahi comes nearly to track. Evidently Mr. Mallett's locality was capped by the Parker. Much a mile to Parker must be over thrust across the Mallett and come to rest on the Dinorahi.

and dip. W. about 10°, then it turns  
around 60° W.

at about 110 yards from road line in  
to me from 40-50 yards

The road is of about 10° - comes about 20°  
east of Highgate road to E. of house at corner of  
road - road dips

Let road house 70 yards from road then in  
a second exposure of Carbon. Eng. to the

Wea. TUES. OCT. 19, 1909 Ther.

Thurs Decs. August 31-1933

Ther. Wea. WED. OCT. 20, 1909 Ther.

Generalized the way of strata between the two houses is about as follows:

On either side of Highgate road here is Corlin congl. of the usual alluvial kind. The thickness is between 20-30 feet.

From the road W. for 290 yards all is either Corlin and Highgate as follows:

In this distance we cross that slopes rapidly to W. or west end.

Eastern limit:

Corlin congl. at least 30 yards across

Highgate slate, 70 yards across, dip  $10^{\circ}$  E.

Sandy dol. 10' thick

Highgate slate 150 yards across. See also a bit

from 40'-50' long.

Highgate slate 40 yards in width of another.

Highgate slate 60 yards to another. At least 100 yards and without ex. of any and wire fence. At least the dip is around  $60^{\circ}$ . We will see the strata west-ly dip again farther south.

Then went S. to the cross road going W. to Woodson farm.

Wea. THUR. OCT. 21, 1909 Ther.

Thursday August 31-1933.

Wea.

FRI. OCT. 22, 1909

Ther.

In front of house east of road down hill - farm  
is the Carlin congl. dipping E. about  $20^{\circ}$ - $25^{\circ}$ . Pres-  
umably a little more in strike here immediately to W.

It is then 250 yards W to the first (N-S) ridge  
and the slip resting on it of the same anticline ori-  
entation described, in this latter instance the di-  
stance is 290 yards, but this distance is taken up  
by the superposition of the latter congl.

The above mentioned ridge is made up of a  
very sandy dol. almost a quartzite hard strata.  
The strata are in a few places thick, and in all is a  
fine grained sand slate or sandy dol. at all 30' thick  
The resting surface of the slate in this case becomes  
 $100^{\circ}$  E where the resting dip is  $20^{\circ}$  to  $30^{\circ}$  W.

Then to W. follows a little shale or argi-  
lous rising into the second ridge seen in the S. of  
road. At the base is a few feet of sand slate. From  
the northern exposure of (200 yards) it is 200 yards  
to W and where it meets the main ridge like  
found and has the same dip. This ridge  
is made up of a very sandy dol. from 20'-30' thick  
and in places it is an intraformational dol. congl  
made of its own material. It dips  $20^{\circ}$  E.

Wea.

SAT. OCT. 23; 1909

Ther.

Thursday, August 31-1933

Wea. SUN. OCT. 24, 1909 Ther.

Beneath the dol. in Highgate slate is a cliff facing west. It also dips  $20^{\circ}$  E.

Farther W. to north of road is an area of thin layers of *Trilobites*, large and small. They are in the Highgate slate, but well beneath the dol. previously mentioned. The other *Trilobites* lies higher above the dol.

Farther west is a swamp with small stream in Champlain clay. This hollow appears to be cut into Highgate slate.

Farther west is the village of East Park slate and to S. of road is the exposure of the Dutch River ls. emb. with at least one *Trilobites*. Both sides of road are on the Emerald farm.

Made another traverse west of Highgate road about  $1/4$  mile N. of second house into the hollow of the stream that goes into Hungford Brook. It is Highgate slate with thin dolomite or other hard zones. The same slate is seen in brook mouth in Hungford Brook.

Wea.

MON. OCT. 25, 1909

Ther.

Thursday August 31 1933

Wea. TUES. OCT. 26, 1909 Ther.

Then went down to Longford Brook, Here all from the road bridge down on the Falls to its base is Highgate slate. On the bottom of the hollow on north bank are exposed 3 dist. layers having a united thickness of 5 feet. These dip N. at about  $15^{\circ}$ . These were seen on an earlier trip.

The center of arch is west of road bridge, since 200 feet <sup>W</sup> of bridge the slope is about  $10^{\circ}$ . Probably the arch is in center of hills causing them in being headward to folding.

From Longford Brook N. to Falls are a plain slope and without hard rock exposures.

Let's see where and how much of the same. Some more as before. These are not yet identified families with this one, all from Brooklyn, the Smith's name.

Wea.

WED. OCT. 27, 1909

Ther.

Friday September 1-1933

Wea. THUR. OCT. 28, 1909 Ther.

Spent most of the morning writing up the observations of yesterday.

In the afternoon restudied the Highgate Gorge sequence and <sup>noted</sup> some striking correlations of the former interpretation. The sequence beneath the Highgate slate is as follows:

The Highgate slate passes gradually into harder and more dolomitic beds. This series appears to be 25' thick, same as of Highgate slate.

The next older beds above Ponce House on north shore of river dip about  $70^{\circ}$  S. or into river.

Below the Highgate thin bedded ls series consists of thin bedded calcareous slate not conglomeratic 3'-4' Calcareous slate, replete with intraformational small angular ls pebbles, averaging 2"-3" and smaller. At the base is a bed 0-6" thick ls, and beneath it a bed 0-10" thick of very shaly bedded ls, pebbles average less than half inch in diameter. Several beds are 5'-6' thick.

Thin bedded blue ls 1'. All seen on S. side of river. Yellowish weathering, fanned massive bed. 1 foot. One small side smaller bed 2' Thin bedded ls as before 1'

Wea.

FRI. OCT. 29, 1909

Ther.

It is in this zone or S. bank that is seen the largest block  
 of bituminous at 10' long and 4' thick. Below it is another one  
 of 10' long by 4' thick. Around and over it are squeezed together  
 bedded banded blue ls = sea bottom sliding. It lies in the  
 upper of this 15' bed with 2' of fine bedded material. <sup>Great [?]</sup>  
 On the south bank these are small out W 7 12'

On the north bank between ① and ② occur thin  
 bedded sh. strata about 10' thick. There too, there  
 are thin separate ls beds. In upper is the magnesian  
 crust. and beneath the 10' is the great breccia  
 layer.

On the south side, then, the breccia bed, it is  
 more nearly a thin material than bedded limestone  
 which that passes W into the 26' great breccia.

FRI. NOV. 5, 1909

Ther.

One of the guests at The Manor <sup>House</sup> ~~ant~~ took  
me to Russell quarry. The dipping is now more  
extensive than ever. Made a new sketch  
of the beds.

Today I concluded that the conglomerate  
bed does not mean a basal one, but rather is  
another bottom slide like those of the Upper Sages.  
Here it is a case of definite bed sliding over  
a shale series. The shale series from the base of  
the slide bed are more or less fractured and  
jumbled and even the mica shale is now dis-  
turbed. That there is no real sedimentation  
is indicated by the lithology since all outside  
of the shale is of the same general character.

In the beds above the shale is a  
time is indicated by the presence of Mich. onera  
Found none today, in fact saw no fossils here  
any kind.

The low ground west from Russell quarry  
to the ridge of dolomite is 200 yards or more.  
In the Russell quarry the dip is about 200E,  
and it is the same for the dist. to the N.W.

Wea.

SAT. NOV. 6, 1909

Ther.

Either this dol. is repeated Mallett or it is the oldest Upper Cambrian. Another mass of it is more than 2000 ft. long and equivalent to the Onitton. I doubt if its thickness is greater than 200 ft. All of it dips E. and plunges N. The dip varies from 20° on the E. to 15° or even 10° on the W.

The dol. first appears half way up the hill and to the top adds but little since one ascends a few feet more.

The dip of these ~~is~~ <sup>are</sup> then bedded dol. is around 10°-15° E. These beds are often seen in the country dol.

Saturday Sept. 2 - 1923.

Wea.

SUN. Nov. 7, 1909

Ther.

The so-called ridge of Mallett begins at about 200 yards west of the Russell quarry. The ascent is up over the dip slope here as on the Russell quarry, about  $N\ 20\ W\ E$ . The gray-white very sandy (and <sup>and in some places</sup> cherty) limestone is overlain by the lower part of the mass in the west where the dip is about  $N\ 45\ E$ . The thickness can be estimated from the topographic map. [about 300']

Below and to the W lies another area of thin bedded grey and light gray sandy, brown (lower part) dolomite. It is also in bedded to the "Mallett" series but probably is older slate, which is clear Parker. These slates in this part of the mass do not have occasional layers of cherty limestone but they meet into a series of thin, gray bedded tri-stratified. I got a number of specimens of cherty limestone, another cherty limestone. In the west I found cherty limestone at the base of the mass. This has in fact has been named Parker slate. The iron ore is in the base
